8 **ABSTRACT**

9
10 Many scientists from different disciplines have studied earthquakes for many years. As a result
11 of these studies, it has been proposed that some changes take place in the ionosphere layer
12 before, during or after earthquakes, and the ionosphere should be monitored in earthquake
13 prediction studies. This study investigates the changes in the ionosphere created by the
14 earthquake with magnitude of Mw=7.2 in the northwest of the Lake Erçek which is located to
15 the north of the province of Van in Turkey on 23 October 2011 and at 1.41 pm local time (-3
16 UT) with the epicenter of 38.75° N, 43.36° E using the TEC values obtained by the Global
17 Ionosphere Models (GIM) created by IONOLAB-TEC and CODE. In order to see whether the
18 ionospheric changes obtained by the study in question were caused by the earthquake or not,
19 the ionospheric conditions were studied by utilizing indices providing information on solar and
20 geomagnetic activities (F10.7 cm, Kp, Dst).

21 One of the results of the statistical test on the TEC values obtained from the both models,
22 positive and negative anomalies were obtained for the times before, on the day of and after the
23 earthquake, and the reasons for these anomalies are discussed in detail in the last section of the
24 study. As the ionospheric conditions in the analyzed days were highly variable, it was thought
25 that the anomalies were caused by geomagnetic effects, solar activity and the earthquake.

26 **Keywords:** TEC, Van Earthquake, Ionosphere

36 1. INTRODUCTION

37 The ionosphere is the part of the atmosphere at the altitudes of 60 km to 1,100 km where there
38 are ions and free electrons in considerable amounts that can reflect electromagnetic waves. It
39 completely covers the thermosphere, one of the main layers of the atmosphere, but also includes
40 some of the mesosphere and the exosphere.

41 Total Electron Content (TEC), which is defined as free electrons along a cylinder with a cross
42 section of 1 m^2 , is a suitable parameter to monitor the changes in the ionosphere. All signals
43 that contain data that pass through or get reflected from the ionosphere, which is highly irregular
44 and difficult to model, are affected by the structure of this layer.

45 Calculating Total Electron Content (TEC) is used directly to investigate the structure of the
46 ionosphere. TEC is represented by the unit of TECU, and one TECU equals to 10^{16} el/m^2
47 (Schaer, 1999). TEC is expressed in two ways: STEC (Slant Total Electron Content); the free
48 electron content calculated along the slanted line between the receiver and the satellite, and
49 VTEC (Vertical Total Electron Content); the free electron content calculated along the zenith
50 of the receiver (Langley, 2002).

51 The ionosphere reacts to geomagnetic effect, solar activity, diurnal and seasonal effects, 11
52 year-solar-cycle, earthquake, and these factors cause irregularities in the ionosphere
53 (Namgaladze et al, 2012, Li and Parrot, 2017).

54 Ionospheric changes have been studied in more than twenty countries today as precursors of
55 earthquakes. Definition of ionospheric anomalies and feasibility studies of seismo-ionospheric
56 precursors are still ongoing (Liu et al., 2010; He et al., 2012; Kamogawa and Kakinami, 2013;
57 Heki and Enomoto, 2015; Pulnits and Davidenko, 2014; Masci et al., 2015; Yildirim et al.,
58 2016; He and Heki, 2017; Kelley et al., 2017;Rozhnoi et al., 2015; Thomas et al., 2017;
59 Ulukavak and Yalcinkaya 2017).

60 2. METHODOLOGY

61 2.1 IONOLAB-TEC Method:

62 The IONOLAB-TEC method developed by the department of Electrical and Electronics
63 Engineering of Hacettepe University is a JAVA application that uses the Regularized TEC (D-
64 TEI) algorithm (Arikan et al. 2004).

65 In this application, they developed a method that estimates VTEC values by using all GPS
66 signals measured at a period of time in a day. While the measurements taken from the satellites
67 with elevations of 60° or higher are used, the measurements from the satellites with elevations
68 of 10° to 60° are weighted by a Gauss function. The data from satellites with elevations of

69 lower than 10^0 are not included in calculations to reduce multipath effects. In this method raw
70 GPS data was used to determine VTEC value.

71 **2.2 Global Ionosphere Model (GIM):**

72
73 Global Ionospheric Maps are published in the IONEX (IONosphere map EXchange) format in
74 a way that covers the entire world. The institutions that produce these maps in the world include
75 CODE (Center for Orbit Determination in Europe, Switzerland), DLR (Fernerkundungstation
76 Neustrelitz, Germany), ESOC (European Space Operations Centre, Germany), JPL (Jet
77 Propulsion Laboratory, California), NOAA (National Oceanic and Atmospheric
78 Administration, United States), NRCan (National Resources, Canada), ROB (Royal
79 Observatory of Belgium, Belgium), UNB (University of New Brunswick, Canada), UPC
80 (Polytechnic University of Catalonia, Spain), WUT (Warsaw University of Technology,
81 Poland). In this study we used the GIM-TEC values produced by CODE in the IONEX format.
82 In the dates they were analyzed, the temporal resolution of the TEC values was 2 hours, while
83 their positional resolution was 2.5^0 by latitude and 5^0 by longitude. In order to calculate TEC
84 values for a point whose latitude and longitude is known on the GIM-TEC maps created by
85 CODE using more than 300 GNSS receivers around the world, the 4 TEC values that cover the
86 point and the two-variable interpolation formula are given below.

$$87 E_{int}(\lambda_0 + p\Delta\lambda, \beta_0 + q\Delta\beta) = (1 - p)(1 - q)E_{0,0} + p(1 - q)E_{1,0} + q(1 - p)E_{0,1} + pqE_{1,1} \quad (1)$$

88 p and q: $0 \leq p, q < 1$.

89 $\Delta\lambda$ and $\Delta\beta$: Longitude and Latitude differences grid widths,

90 λ_0 and β_0 : Initial longitude and latitude values,

91 $E_{0,0}, E_{1,0}, E_{0,1}$ ve $E_{1,1}$: TEC values known in neighboring points,

92 E_{int} : TEC value to be found.

93 **3. ANALYSIS TO DETERMINE EARTHQUAKE-RELATED TEC CHANGES**

94
95 In order to investigate earthquake-related TEC changes, the TEC values for OZAL station
96 (TUSAGA-Active CORS-TR) close to the epicenters GPS station was analyzed to determine
97 TEC value using the IONOLAB-TEC and GIM-TEC models. The correlation coefficient was
98 obtained for the TEC values from both models between the dates 13.10.2011 and 02.11.2011
99 for the stations above. In addition to that, spatial analysis was applied to determine distribution
100 characteristics of the ionospheric changes.

101
102

Figure 1. Demonstration of analyzed station

103 Figure 1 shows the stations analyzed (represented by red triangles) and the epicenter of the
 104 earthquake represented by blue star. TEC values with the temporal resolution of two hours
 105 obtained from both the IONOLAB-TEC and GIM-TEC models for OZAL station which is
 106 nearest station to epicenter of earthquake and the correlation coefficient was computed to
 107 explain linear relationship between two models. On the other hand, TEC values were also
 108 obtained using GIM model to explain spatial changes of ionosphere for IZMI, AFYN, KAYS
 109 and BING stations.

$$110 \quad r = \frac{1}{n-1} \Sigma \left(\frac{X-\bar{X}}{S_X} \right) \Sigma \left(\frac{Y-\bar{Y}}{S_Y} \right) \quad (2)$$

111

112 In order to determine the outlier values among the TEC values with a two-hour temporal
 113 resolution from both models, the TEC values obtained from both models between the dates
 114 01.10.2011 and 10.10.2011, which were considered quiet in terms of geomagnetic and solar
 115 activity, were used to determine the upper boundary (UB) and the lower boundary (LB). By
 116 utilizing the TEC values from both models, the UB and LB values were calculated using the
 117 formulae $x+3\sigma$ and $x-3\sigma$. Here, x is the mean TEC value for the relevant epoch and σ is the
 118 standard deviation. If the TEC value in any epoch is higher than the upper boundary, it is a
 119 positive anomaly. Similarly if it is lower than the lower boundary, it is a negative anomaly. In
 120 order to investigate whether the anomalies before, on the day of and after the earthquake were
 121 caused by the earthquake or not, we also examined the (K_p*10), Dst and F10.7 cm indices,
 122 which provided information on the geomagnetic and solar activity for the days in which
 123 anomalies were detected.

139

Table 2. OZAL Station IONOLAB-TEC Anomaly Table

140

141 The correlation coefficient r between the TEC values calculated by both methods for the OZAL
 142 station was 0.98 demonstrating a strong positive relationship. The anomaly tables for this
 143 station are provided below (Tables 1 and 2).

144 In order to determine whether anomalies caused by earthquake or not, we also monitored spatial
 145 changes of TEC. In this regard, we investigated IZMI, AFYN, KAYS, BING stations TEC
 146 changes using GIM models. These receivers are located in same latitude as the OZAL station,
 147 thus we can obtain spatial TEC changes in Turkey for analyzed days.

Table 6. BING Station GIM-TEC Anomaly Table

166
167

168 The tables (1-6) also depict the day and hour in which anomalies were observed, and the amount
169 and type of the anomaly. The numbers of anomalies obtained in both models were very close
170 to each other. The F10.7 cm index values between the days 288 and 292 were 136.9 sfu, 150
171 sfu, 151.6 sfu, 145.7 sfu, 146.1 sfu. The index values show that there was usually moderate
172 solar activity. Therefore, the anomalies in question may be related to the earthquake or solar
173 activity. The index values for the days 293, 294, 295 and 296 (the day of the earthquake) were
174 157.8 sfu, 166.3 sfu, 162.5 sfu and 153.9 sfu respectively. These values indicate strong solar
175 activity. On the other hand, the ionosphere layer was quiet in these days in terms of geomagnetic
176 conditions. As there was strong solar activity, the numbers of anomalies were higher than the
177 numbers in the days 288-292. Since solar activity was moderate in the day 297, the number of
178 anomalies dropped. The solar activity on the day 298 was moderate, but there was strong
179 geomagnetic activity (Dst -147 nt, Kp*10=73). The reason for the high numbers of anomalies
180 on day 298 in both models is believed to be due to geomagnetic activity. This magnetic storm
181 has caused different amount of TEC variation for all stations.

182 As another indicator, we extract Σ A TEC (Totally TEC difference) to determine total amount of
183 anomaly day by day for each analyzed days.

184

Stations/A nomaly Day	288 (Σ AT EC)	289 (Σ AT EC)	290 (Σ AT EC)	292 (Σ AT EC)	293 (Σ AT EC)	294 (Σ AT EC)	295 (Σ AT EC)	296 (Σ AT EC)	297 (Σ AT EC)	298 (Σ AT EC)
IZMI- GIM	-	0.2	-	1.8	0.1	3.9	2	6.2	2.1	28.5
AFYN- GIM	4.5	-	-	2.3	2.2	8	3.3	8	3.2	31.4
KAYS- GIM	4.6	1.2	0.1	2.1	4	12.2	4.1	9.2	3.9	34.5
BING- GIM	5.6	2.1	0.4	1.4	5	15.8	5.6	9.6	4.1	39.1
OZAL- GIM	7.7	2.5	0.5	0.8	5.2	15.2	6.2	9.4	4.1	44.5

Table 7. Total amount of anomaly in TECU for analyzed days

185
186

187 Table 7 shows total anomaly summary results obtained from analysis results. Positive
188 anomalies were observed before and after the earthquake and amount of anomaly is nearly equal

189 to each other in this earthquake. In addition to that, Σ A TEC differences between stations are
190 also similar to each other for in each analyzed day.

191 Considering the analyzed days in general for all stations, it may be seen that it is difficult to
192 identify earthquake-related anomalies as the solar activity and geomagnetic conditions before
193 and after the earthquake were not quiet. Therefore, it is believed that the anomalies detected in
194 the stations on days 293-296 may be related to the earthquake and/or solar activity, and the
195 anomalies on days 297 and 298 may be related to the earthquake, solar activity and/or
196 geomagnetic activity.

197

198 **DISCUSSION AND CONCLUSION**

199 Seismic ionospheric evaluations of Van earthquake have also been studied by many researchers
200 (Arikan et al., 2012; Zolotov et al., 2012; Rolland 2013; Şentürk et al., 2018). (Arikan et al.,
201 2012; Zolotov et al., 2012) determined some anomalies before and after the earthquake, but
202 solar and magnetic conditions were not taken into account. On the other hand (Şentürk et al.
203 2018) also obtained abnormal days before and after the earthquake and They evaluated solar
204 activity and magnetic storm conditions for these abnormal days to explain possible causes of
205 anomalies in detail. Some previous studies have also studied on both space weather and
206 earthquake effect in the ionosphere (Yao et al., 2012; Le et al., 2013). They especially state that
207 TEC enhancement may be related to geomagnetic storm and earthquake.

208 (Şentürk et al., 2018) study also shows that there is no obvious anomaly caused only by
209 earthquake. Therefore they suggest that A multidisciplinary study would be useful to identify
210 ionospheric changes as an earthquake precursor under the disturbed space-weather conditions.
211 This approach shows that their results agree with our study.

212 In the scope of this study, the TEC values for the stations IZMI, AFYN, KAYS, BING were
213 obtained using the GIM-TEC and TEC values were also obtained using GIM-TEC and
214 IONOLAB-TEC methods for OZAL station. In the comparison of the obtained values, it was
215 seen that there was high correlation between the TEC values obtained by the two models for
216 OZAL station. In order to detect earthquake-related TEC changes better, the TEC values created
217 from both models for the period of 13.10.2011-02.11.2011 were used as reference to determine
218 the upper bound and lower bound values. As a result of the statistical test, anomalies were found
219 in all analyzed stations for before, on the day of and after the earthquake. In order to understand
220 whether the anomalies obtained in both models were earthquake-related, the ionospheric
221 conditions, geomagnetic activity and solar activity on the analyzed days were examined using
222 the Kp, Dst and F10.7 cm indices.

223 Consequently, it was determined that the positive anomalies observed on days 286-292 may be
224 related to moderate solar activity and/or the earthquake, and the positive anomalies observed
225 on days 293, 294, 295, 296 (day of the earthquake) may be related to strong solar activity and/or
226 the earthquake. Moderate solar activity and strong geomagnetic activity were observed for day
227 298, so the numbers of anomalies in both models increased dramatically. This increase is
228 considered to be related to geomagnetic activity. The anomaly on day 298 may be related to the
229 earthquake, geomagnetic effects and/or solar activity. The finding that the ionospheric
230 conditions were variable in the analyzed days makes it highly difficult to identify earthquake-
231 related ionospheric changes. Therefore, interdisciplinary study is needed to determine the
232 earthquake-related part of the change in question.
