15 **Abstract:** In this study, we focused on the retrieval of atmospheric water vapor
16 density by optimizing the tomography technique. First, we established a new
17 atmospheric weighted average temperature model that considers the effects of
18 temperature and height, assisted by Constellation Observing System for Meteorology,
19 Ionosphere and Climate (COSMIC) products. Next, we proposed a new method to
20 determine the scale height of water vapor, which will improve the quality of vertical
21 constraints. Finally, we determined the smoothing factor in the horizontal constraint
22 based on Interim European Centre for Medium-Range Weather Forecasts (ECMWF)
23 Re-Analysis (ERA-Interim) products. To evaluate the advantages of the optimized
24 technique over the traditional method, we used GPS datasets collected in Hong Kong
25 in August 2016 to estimate the vertical distribution of water vapor density using both
26 methods. We further validated the tomography results from the optimized technique

26 using radiosonde products. The results show that the water vapor density quality
27 obtained by the optimized technique is 13.8% better below 3.8 km and 8.1% better
28 above 3.8 km than that obtained by the traditional technique. We computed the
29 success rate of the tomography technique based on the Pearson product-moment
30 correlation coefficient (PCC) and root mean square (RMS). The success rate of the
31 optimized topography technique was approximately 10% higher than that of the
32 traditional tomography method.

33 **Keywords:** GPS radio occultation; water vapor; GPS tomography; atmospheric
34 weighted average temperature

35 **Introduction**

36 GPS technology has recently started being used to detect the Earth's atmosphere.
37 Many studies have been carried out to retrieve the two-dimensional (2D) or
38 three-dimensional (3D) distribution of atmospheric water vapor (Flores et al., 2001;
39 Champollion et al., 2005; Nilsson et al., 2006; Jin et al., 2009; Esteban et al., 2013;
40 Jiang et al., 2014; Chen et al., 2014). The obtained atmospheric water vapor product
41 can be assimilated into a numerical weather prediction (NWP) model. By applying the
42 NWP model to weather forecasting, we have discovered the usefulness of GPS
43 tomography to estimate water vapor distribution (Jin et al., 2011; Esteban et al., 2013).
44 Combined with the space-based GNSS (Global Navigation Satellite System)
45 occultation technique, it can provide neutral atmosphere products with high precision,
46 high vertical resolution, and low-cost, near-real-time, all-weather global coverage. In
47 addition, it can contribute to scientific research on the ionosphere (Kursinski et al.,
48 1997; Rocken et al., 1997; Hajj et al., 2002; Kuo et al., 2007).

49 In ground-based GPS meteorology, GPS signal propagation through the atmosphere
50 is slowed, thus causing path delay on the GPS measurements, which is termed
51 tropospheric delay (Kouba and Héroux, 2001). Zenith total delay (ZTD) is one of the
52 most important error sources in GNSS navigation and positioning; however, it is a
53 very reliable information source in GNSS meteorology (Jacob et al., 2007; Jin et al;
54 2007; Jin et al; 2009; Falconer et al., 2009). ZTD consists of two parts: zenith wet
55 delay (ZWD) and zenith hydrostatic delay (ZHD) (Davis et al., 1985). Usually, ZHD
56 can be calculated with high accuracy from empirical models, and ZWD can then be
57 easily derived from ZTD based on formula $ZWD=ZTD-ZHD$. Afterward, slant wet
58 delay (SWD) can be obtained from ZWD based on the wet Niell mapping function
59 (Niell, 1996). Both ZWD and SWD are related to atmosphere water vapor, and thus
60 precipitable water vapor (PWV) and slant water vapor (SWV) can be derived from
61 ZWD and SWD using the humidity conversion coefficient (Song, 2004).

62 ZHD is usually estimated in GNSS meteorological research using the Saastamoinen
63 model (Flores et al., 2000; Troller et al., 2006; Champollion et al., 2009; Perler et al.,
64 2011; Jiang et al., 2014). The atmospheric weighted mean temperature T_m is the key
65 variable to obtain high-precision humidity conversion coefficient (Mateus et al., 2014).
66 T_m will differ significantly as the season varies and the region changes (Jin et al.,
67 2008). It can be determined by the surface temperature measurement, which is
68 provided by a radiosonde product or other meteorological data analyses (Bevis et al.,
69 1992; Wang et al., 2011).

70 In space-based GNSS meteorology, GNSS radio occultation (RO) is regarded as a

71 valuable data source for atmospheric change studies (Rocken et al., 1997; Kursinski et
72 al., 1997; Hajj et al., 2002; Beyerle et al., 2005). The Constellation Observing System
73 for Meteorology, Ionosphere and Climate (COSMIC) is housed within the University
74 COporation for Atmospheric Research (UCAR). The mission of the COSMIC RO is
75 to develop the weather, climate, space weather and geodetic research (Yen et al.,
76 2007). The University Corporation for Atmospheric Research/COSMIC Data
77 Analysis and Archive Center (UCAR/CDAAC) supplies two different types of
78 products from the COSMIC mission: real-time data and post-processed data products.
79 Of these post-processed products, wet atmospheric profiles (wetPrfs) offer water
80 vapor pressure, temperature, etc. Shi et al. (2009) compared the bias of PWV between
81 wetPrf-derived and precise point positioning (PPP)–derived data and suggested that
82 they have comparable accuracy levels. Kishore et al. (2011) discussed the difference
83 in specific humidity between wetPrfs and radiosonde data. They concluded that both
84 sources have good correlation (~ 0.8) up to 8 km and that the humidity information of
85 wetPrfs is reliable up to nearly 8 km. In addition, Wang et al. (2013) studied the
86 accuracy of wetPrfs using the Radiosonde products as the reference and revealed that
87 a global mean temperature deviation of -0.09 K and a global mean humidity deviation
88 is better than -0.12 g/kg in the pressure range of 925 to 200 hPa.

89 To improve the accuracy of water vapor derived using the GNSS technique, we
90 optimized several key techniques for GNSS tomography. First, we precisely derived
91 the T_m model using wetPrf profiles, then determined the regional humidity conversion
92 coefficient. Next, for vertical constraints, we used a new way to determine the scale

93 height of water vapor in the exponential model. Finally, we derived the smoothing
94 factors of the Gauss distance weighting function in the horizontal constraint using
95 Interim European Centre for Medium-Range Weather Forecasts (ECMWF)
96 Re-Analysis (ERA-Interim) products. We used GPS datasets from Hong Kong in
97 August 2016 to evaluate this new method. The results demonstrate better accuracy
98 than those of the traditional method with radiosonde data.

99 The rest of this paper is organized as follows. Section 2 introduces the principles of
100 GNSS tomography and the optimized technique for establishing the atmospheric
101 weighted average temperature model and deriving the scale height of water vapor.
102 Section 3 describes the data processing. Section 4 presents the validation of the
103 optimized method, and the quality control process for the tomography results. The
104 discussions and conclusions are given in Section 5.

105 **2. GNSS Tomographic formulation**

106 In this section, we first introduce the GPS tomography model. We then illustrate the
107 optimized techniques for the ZHD model and the humidity conversion coefficient
108 determination. Finally, we present the constraint model.

109 **2.1 Tomographic technique**

110 To reconstruct 3D images of water vapor density distributions, the SWV along ray
111 paths traversing the imaged region should first be obtained from dual-frequency
112 GNSS data. This is defined by the line integral of water vapor density along the ray
113 path from satellite to receiver (Flores et al., 2001), as follows:

$$114 \quad SWV = \frac{1}{\rho_w} \cdot \left(\int_s \rho(s) ds \right) \quad (1)$$

115 where ρ_w means the density of liquid water, s denotes the trajectory of GNSS signals
116 in the troposphere, and $\rho(s)$ indicates the water vapor density.

117 Eq. (1) reveals that the accuracy of water vapor density mainly depends on the
118 quality of the SWV. Generally, ZTD can be precisely estimated using the
119 double-difference or PPP method. ZWD can be obtained by removing ZHD from
120 ZTD. After the humidity conversion coefficient is determined, the SWV will be
121 computed providing that the SWD is known (MacMillan, 1995), as follows:

$$122 \quad SWD = STD - SHD - \Delta L_{gradient} \quad (2)$$

$$123 \quad \Delta L_{gradient} = \frac{1}{\sin(e) \cdot \tan(e) + C} \cdot (G_N \cdot \cos(\alpha) + G_E \cdot \sin(\alpha)) \quad (3)$$

$$124 \quad PWV = \Pi \cdot ZWD \quad (4)$$

$$125 \quad SWV = \Pi \cdot SWD \quad (5)$$

126 where STD and SHD are slant troposphere delay and slant hydrostatic delay,
127 respectively; $\Delta L_{gradient}$ means the horizontal gradient; G_N and G_E are the north and east
128 atmosphere horizontal gradients, respectively; e and α are the satellite elevation angle
129 and the azimuth angle, respectively; C is a constant with as $C=0.003$ (Chen and
130 Herring, 1997); and Π means the humidity conversion coefficient. SWD and SHD can
131 be projected to ZWD and ZHD based on the Niell mapping function (Niell, 1996).
132 From Eq. (2) and Eq. (5), we know that the accuracy of the ZHD and the humidity
133 conversion coefficient are the crucial aspects that affect SWV quality. Thus, it is
134 essential to develop a high-precision ZHD model and humidity conversion coefficient.

135 2.2 Humidity conversion coefficient

136 The humidity conversion coefficient Π can be expressed as a function of T_m . T_m varies
 137 across seasons and areas and depends mainly on the surface atmosphere temperature
 138 (Bevis et al., 1994), as follows:

$$139 \quad \Pi = \frac{10^6}{\rho_w \cdot \frac{R}{m_w} \cdot \left[\frac{k_3}{T_m} + k_2 \frac{m_w}{m_d} \cdot k_1 \right]} \quad (8)$$

$$140 \quad T_m = \frac{\int_{h_0}^{\infty} \left(\frac{P_w}{T} \right) \cdot dh}{\int_{h_0}^{\infty} \left(\frac{P_w}{T^2} \right) \cdot dh} = \frac{\sum \frac{(h_2 - h_1) P_w}{T}}{\sum \frac{(h_2 - h_1) P_w}{T^2}} \quad (9)$$

141 where ρ_w is the density of liquid water; k_1 , k_2 and k_3 are constants— $k_1 = 77.6$ K/hPa, k_2
 142 $= 70.4$ K/hPa and $k_3 = 3.739 \cdot 10^5$ K/hPa (Bevis, 1994); T_m is the atmospheric weighted
 143 average temperature; m_d and m_w mean the molar masses of dry atmosphere and water
 144 vapor, respectively; R indicates the universal gas constant; P_w indicates water vapor
 145 pressure in units of hPa; T is the atmosphere temperature and h means the height.

146 2.3 Constraint model

147 Usually, the observation equation of the tomographic approach is rank deficient
 148 because the GPS signal cannot pass through all of the grids. Horizontal constraints,
 149 vertical constraints, priori information value constraints, and boundary constraints
 150 must be added to avoid this deficiency. With these constraints, we can use an iterative
 151 reconstruction algorithm, or a non-iterative reconstruction algorithm to resolve the
 152 tomography equation.

153 The horizontal constraint is the Gauss distance weighting function (Song, 2004), as
 154 follows:

$$155 \quad B = \frac{\exp\left(\frac{-d_{i,j,k}^2}{2\delta^2}\right)}{\sum_{i=1}^{nl} \sum_{j=1}^{nn} \exp\left(\frac{-d_{i,j,k}^2}{2\delta^2}\right)} \quad (10)$$

156 where B is the horizontal smoothing; the subscript i,j,k means the index of voxel in 3D
 157 space; nl and nn are the numbers of the grids in the east–west and north–south
 158 directions, respectively; $d_{i,j,k}$ indicates the distance between known and unknown
 159 water vapor grids; and δ denotes the smoothing factor, which will change at different
 160 levels. Section 3.3.1 explains how to estimate δ .

161 The vertical distribution of water vapor does not follow the ideal-gas law,
 162 particularly in the lower levels. Currently, there is no accurate model function to fit the
 163 spatial distribution of water vapor. The vertical constraint of atmospheric tomography
 164 can be obtained using an exponential model (Jiang et al., 2014; Ye et al., 2016), as
 165 follows:

$$166 \quad \rho(h) = \rho_0 \cdot \exp\left(-\frac{h-h_0}{H_{we}}\right) \quad (11)$$

167 where $\rho(h)$ is the water vapor density at the height of h ; ρ_0 is the water vapor density at
 168 the height of h_0 ; and H_{we} is the scale height of water vapor. ρ_0 , h_0 and H_{we} can usually
 169 be determined using radiosonde or COSMIC historical data. In this case, the estimated
 170 $\rho(h)$ is only an experience value and will have a greater error than the true value.
 171 Therefore, we propose a new method to estimate $\rho(h)$ and H_{we} in near-real-time.

172 Based on Eq. (2) and the Niell mapping function (Niell, 1996), ZWD can be
 173 estimated in real-time. PWV can then be obtained according to Eq. (4). The
 174 relationship between PWV and $\rho(h)$ is established as follows:

$$175 \quad PWV = \frac{1}{\rho_w} \cdot \int_{h_0}^{h_{top}} \rho(h) dh \quad (12)$$

176 where ρ_w is the density of liquid water; h_0 is the height of station and h_{top} is the
 177 height of tropopause. Combining Eq. (11) and Eq. (12), we get:

178 $PWV =$

$$179 \frac{1}{\rho_w} \cdot \int_{h_0}^{h_{top}} \rho(h) dh = \frac{1}{\rho_w} \cdot \int_{h_0}^{h_{top}} \rho_0 \cdot \exp\left(-\frac{h-h_0}{H_{we}}\right) dh = \frac{\rho_0 \cdot H_{we}}{\rho_w} \left[1 - \exp\left(-\frac{h_{top}-h_0}{H_{we}}\right)\right] \cong$$

$$180 \frac{\rho_0 \cdot H_{we}}{\rho_w} \quad (13)$$

181 The parameter H_{we} can be derived in real-time using Eq. (13). Based on Eqs. (11)
 182 and (13), Eq. (14) can be utilized to establish the functional relationship in the vertical
 183 direction, as follows:

$$184 \frac{\rho_{i,j,k+1}}{\rho_{i,j,k}} = \exp\left(-\frac{h_{k+1}-h_k}{h_{we}}\right) \quad (14)$$

185 where $\rho_{i,j,k}$ represents the water vapor value of datum voxel (i,j,k) .

186 The priori humidity information can be used for the background field of troposphere
 187 tomography, and will enhance the computing speed and tomography accuracy. The
 188 synoptic observation data include the atmosphere pressure, atmosphere temperature,
 189 and relative humidity observed in the station and the atmosphere temperature and
 190 relative humidity can be interpolated into all of the voxels using Eqs. (10) and (14).
 191 Thus, the water vapor density of every voxel can be calculated (Jiang et al., 2014).

192 3. Data processing

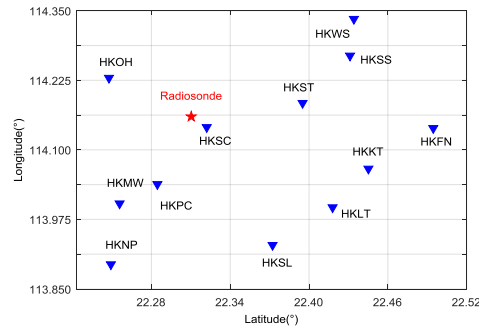

193 3.1 Data collection

194 Data used to remote sense atmospheric water vapor contain ground-based GNSS
 195 observations and meteorological data, and space-based COSMIC wet profiles.
 196 UCAR/CDAAC supplies two different types of products: real-time profiles and

197 post-processed profiles. The former can be available within a few hours and the latter
198 can be available with a 6-week latency (www.cosmic.ucar.edu). We selected
199 post-processed profiles in this study. Wet profiles (wetPrfs) are one type of COSMIC
200 post-processed products that are freely available for public access
201 (<http://cdaac-www.cosmic.ucar.edu/cdaac/>). wetPrfs are interpolated products
202 sampled at 100-m intervals and obtained using a nonstandard one-dimensional
203 variation technique together with European Centre for Medium-Range Weather
204 Forecasts (ECMWF) low-resolution analysis data from altitude of the perigee point
205 from the surface to a 40-km altitude (CDAAC., 2005a). The average bias of
206 temperature between wetPrfs and radiosonde is less than 0.1 K, 70% - 90% of the
207 wetPrfs reach to within 1 km of the surface on a global basis.
208 (<http://www.cosmic.ucar.edu/ro.html>).

209 We used ground-based GNSS observations and meteorological products from the
210 Hong Kong SatRef network (<https://www.geodetic.gov.hk/>), from 12 continuously
211 operating reference stations with an inter-station distance of 7 to 27 km, covering
212 approximately 1100 km². All 12 stations were equipped with “LEICA
213 GRX1200+GNSS” receivers and had data sampling rates of 5 seconds, as shown in
214 Fig. 1. The meteorological data associated with each GPS station at 60-second
215 intervals is freely available at <https://www.geodetic.gov.hk/>. GPS datasets from
216 August 1, 2016 to August 31, 2016 were collected daily in Hong Kong. wetPrfs in or
217 near Hong Kong in August of 2009–2015 were downloaded.

218

219

Fig. 1. Distribution of the Hong Kong SatRef sites (blue triangles) inside the tomography

220

horizontal grid (black dotted lines) and the KingPark radiosonde station (red star). The region was

221

discretized into an $8 \times 5 \times 17$ cell grid for the GPS water vapor tomography. The layer heights are

222

0, 400, 800, 1400, 2000, 2600, ..., 8600 from ground to water vapor layer top.

223

224

The reconstruction region covered an area ranging from latitude 22.22 to 22.52 N,

225

longitude 113.85 to 114.35 E, and from ground to water vapor layer top (WVLT) in

226

height. Thus, the entire area of Hong Kong was divided in to 5×8 horizontal grids

227

and 17 vertical layers. A total of $8 \times 5 \times 17 = 680$ voxels were divided in the 3-D

228

space.

229

3.2 Regional weighted average temperature model

230

Bevis et al. (1994) first put forward the global T_m model using radiosonde products.

231

Later, Wang et al. (2011) established the T_m model in Hong Kong using radiosonde

232

products. Ye et al. (2016) also assessed the relationship between T_m and surface

233

temperature based on radiosonde and COSMIC products. However, these three

234

models only consider the parameter of surface temperature. We propose considering

235 the effects of temperature and height to establish a T_m model using COSMIC products.

236 The new model is given as follows (Yao et al., 2013):

$$237 \quad TmN = a + b \cdot T_h + c \cdot T_h^2 + e \cdot h + f \cdot h^2 \quad (15)$$

238 where a , b , c , e and f are constants that can be determined using COSMIC products;

239 T_h indicates the temperature at height h ; h denotes the height; and TmN is the new
240 model value of T_m .

241 The weighted average temperature T_m is obtained using Eq. (9) with input wet
242 pressure and temperature provided from wetPrfs. TmN can be derived using Eq. (15);
243 its values are shown in Fig. 2. The wetPrfs described in Section 3.2 are used to derive
244 the humidity conversion coefficient from Eq. (8).

245

246 **Fig. 2.** Considering height and surface temperature to establish the T_m model using wetPrf

247 products. T_0 is the surface temperature; and TmC is the fitted atmospheric weighted average

248 temperature obtained from COSMIC products for 2009 to 2015 in Hong Kong.

249

250 As shown in Fig. 2, the new model's T_m values agree well with the true values. To
251 evaluate the new T_m model, its values are compared with those obtained from
252 radiosonde and COSMIC products. Fig. 3 shows the results for Hong Kong in August
253 2016.

254
255 **Fig. 3.** New T_m model values are compared with those derived from COSMIC and
256 radiosonde products in Hong Kong in August 2016. TmC is the T_m derived from COSMIC
257 products; TmN is the T_m derived from the new model; TmB is the T_m derived from the Bevis model;
258 TmW is the T_m derived from the Wang model; and TmR is the T_m derived from radiosonde
259 products.

260
261 The statistical results comparing the model-derived and COSMIC-derived T_m are
262 given in Table 1. We provide a summary of the T_m deviation between
263 radiosonde-derived and model-derived data in Table 2.

264 **Table 1.** Summary of the T_m deviation between COSMIC-derived and model-derived (K) data.

	Max.	Min.	Mean	RMS
TmC-TmN	2.2	-4.7	-0.5	1.7
TmC-TmB	6.3	-2.1	2.2	2.9
TmC-TmW	2.1	-5.7	-1.5	2.3

265 **Table 2.** Summary of the T_m deviation between radiosonde-derived and model-derived (K) data.

	Max.	Min.	Mean	RMS
TmR-TmN	4.7	-5.2	-0.1	2.4
TmR-TmB	6.1	-2.8	2.1	3.0
TmR-TmW	3.4	-6.4	-0.9	2.4

266 As shown in Tables 1 and 2, the new T_m model improves the accuracy of
267 atmospheric weighted average temperature from the Bevis model and Wang
268 model.

269 3.3 Tomography constraint condition

270 3.3.1 Estimating the smoothing factor

271 The smoothing factor δ in Eq. (10) is an uncertain parameter in the horizontal
272 constraint. Usually, it is assigned a constant value of experience (Xia et al., 2013;
273 Jiang et al., 2014). Because δ varies with regions and seasons and also changes with
274 different levels of tomography model, ERA-Interim data for Hong Kong from August
275 2009 to August 2015 were used to precisely estimate δ . ERA-Interim is a reanalysis of
276 the global atmosphere covering the data-period since 1989, and continuing in real
277 time (<http://apps.ecmwf.int/datasets/data/>). The specific humidity data with 60 levels
278 of vertical spatial resolution and a minimum grid of $0.125^{\circ} \times 0.125^{\circ}$ are publicly
279 available. The main characteristics of the ERA-Interim system and many aspects of its
280 performance are described in ECMWF newsletters 110, 115, and 119
281 (<http://www.ecmwf.int/publications/newsletters>). In addition, comprehensive

282 documentation of ERA-Interim, including observation usage, is currently being
 283 prepared and will be made available at <http://www.ecmwf.int/research/era>.

284 In each level, the humidity information of one grid point equals the weighted
 285 average of its neighbors (Rius et al., 1997), as follows:

$$286 \quad 0 = B_1\rho_1 + B_2\rho_2 + \dots + B_{j-1}\rho_{j-1} - \rho_j + B_{j+1}\rho_{j+1} + \dots \quad (16)$$

287 According to the humidity information provided by ERA-Interim, Eq. (16) can be
 288 solved using the optimal parameter search method. The search step is set to 1 and the
 289 search range is [0, 20]. The value of δ is exactly equal to the number of grid points in
 290 each level, and we defined the mean of δ as the smoothing factor of the level. Table 3
 291 lists the δ values at different heights using ERA-Interim data for Hong Kong from
 292 August 2009 to August 2015.

293 **Table 3.** Smoothing factor derived by ERA-Interim products at different heights.

Height range (km)	0	0.4	0.8	1.4	2	2.6	3.2	3.8	4.4	5.0	5.6	6.2	6.8	7.4	8.0	8.6
δ (integer)	8	8	7	6	5	8	4	7	6	6	4	4	4	4	4	4

294 Table 3 shows that the smoothing factors present a nonlinear change for increasing
 295 heights below 6 km, but do not change between 6 and 9 km. The horizontal constraint
 296 can be accurately determined based on the smoothing factor and the distance between
 297 known and unknown grids.

298 3.3.2 Vertical constraint

299 The purpose of GNSS tomography technique is to derive the 3-D distribution of water
 300 vapor. Thus, the accuracy of the vertical constraint will directly affect the quality of
 301 the tomography results. Because water vapor randomly varies in time-space, it is
 302 difficult to precisely probe the spatial distribution of water vapor. Traditionally, Eq.

303 (14) was used as a vertical constraint and the parameter H_{we} could be obtained using
304 COSMIC or radiosonde historical data products (Ye et al., 2013; 2016). Due to H_{we}
305 changes over time are obvious, so they need to be obtained once for each tomography
306 epoch. In this paper, PWV was derived using Eq. (4), and H_{we} was then derived in real
307 time based on Eq. (13). To evaluate the accuracy of H_{we} , the radiosonde-obtained
308 water vapor is used as references to assess the water vapor calculated using Eq. (11).
309 The statistical results are given in Table 4 using the “45004th” radiosonde station (lat:
310 22.32; lon: 114.16) and HKSC station (lat: 22.32; lon: 114.14) datasets from August
311 2016 under 10 km.

312 **Table 4.** Statistical results from Eq. (11)-derived and radiosonde-derived PWV (g/m^3). RWV is the
313 water vapor density obtained from the radiosonde product; TWV is the water vapor density
314 derived from the H_{we} obtained by the traditional method using Eq. (11); NWV is the water vapor
315 density derived from the H_{we} obtained by the new method using Eq. (11).

	RMS	Mean
RWV-TWV	8.29	-3.29
RWV-NWV	5.15	-2.87

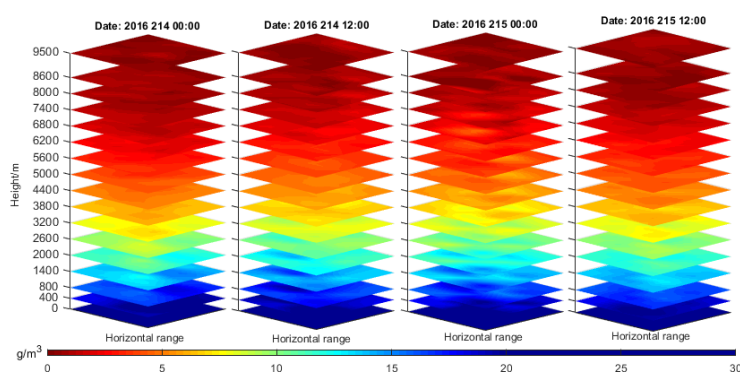

316 As shown in Table 4, the water vapor density derived from the H_{we} obtained using
317 the new technique and Eq. (11) is closer to the radiosonde-derived water vapor density.
318 Therefore, it is more reasonable to use the H_{we} obtained using the new technique and
319 Eq. (14) as the vertical constraint.

320 4. Result validation and analysis

321 To evaluate our optimized method, we obtained ZTDs from the Hong Kong SatRef
322 network in August 2016, based on Bernese 5.2 (non-difference) software. The ZHDs

323 were estimated using the Saastamoinen mode. The SWV was then obtained using the
324 Niell mapping function (Niell, 1996) and the calibrated humidity conversion
325 coefficient. The WVLТ was determined as 9.5 km from COSMIC historical data and
326 Ye et al.'s (2016) method. Following the tomography model proposed by Flores et al.
327 (2000), we estimated the 3D water vapor distribution using the GPS tomography
328 technique with the horizontal constraint from Eq. (10) and the vertical constraint from
329 Eq. (14). The tomography equation was solved adopting Kalman filtering. The
330 tomography results were outputted once every 30 minutes. As we have limited space,
331 Fig. 4 only shows the 3D distribution of water vapor density on August 1, 2016 and
332 August 2, 2016.

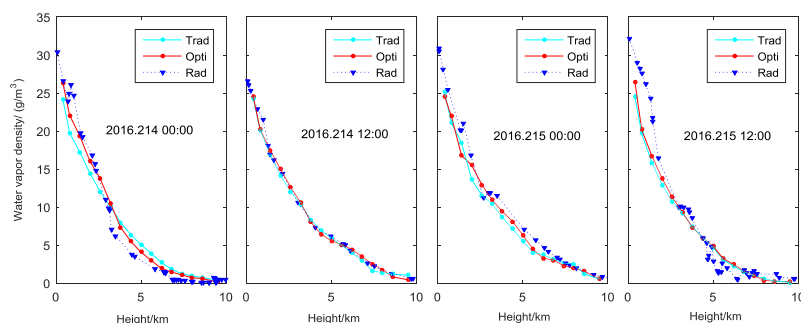

333
334 **Fig. 4.** 3D tomographic water vapor distribution in Hong Kong on August 1, 2016 and August 2,
335 2016.

337 Figure 4 presents the 3D tomographic water vapor distribution in Hong Kong for
338 heights lower than 9.5 km. The results show that the water vapor changes significantly
339 below 3.8 km, whereas it remains stable above 3.8 km. In addition, the water vapor is
340 mainly concentrated below 2.6 km.

341 4.1 Compare the results between tomography-obtained and radiosonde-obtained
342 Radiosonde products contain 3-D distribution of meteorological elements such as
343 atmosphere temperature, atmosphere pressure, mixing ratio, and relative humidity. The
344 “wet” pressure can be obtained based on the pressure and mixing ratio and can be
345 utilized to compute the water vapor density (Song, 2004). To verify the advantage of
346 the optimized GPS tomography method, using radiosonde products as references, the
347 tomography results were compared with those derived from the traditional tomography
348 technique using the Saastamoinen dry model, traditional humidity conversion
349 coefficient (0.1538), smoothing factor (10) and H_{we} obtained using the traditional
350 technique and COSMIC historical products. Fig. 5 compares the water vapor densities
351 derived from radiosonde products and the traditional and optimized tomography
352 techniques for August 1, 2016 and August 2, 2016.

353
354 **Fig. 5.** Water vapor densities obtained from tomography-derived and radiosonde-derived data. Rad
355 is the water vapor density derived using radiosonde products; Trad is the water vapor density
356 derived using the traditional tomography method; and Opti is the water vapor density derived
357 using the optimized method.

358 It can be observed in Fig. 5 that the changing trends of water vapor with height
 359 across the tomography-obtained and radiosonde-obtained have a good agreement.
 360 However, when the “inversion layer” occurs, GPS tomography cannot accurately
 361 reflect this situation. In Table 5, we present the deviation statistics for GNSS
 362 tomography-obtained and radiosonde-obtained water vapor density at heights above
 363 and below 3.8 km, using 31-day datasets from Hong Kong over the whole of August
 364 2016.

365 **Table 5.** Statistics for tomography-derived and radiosonde-derived water vapor density above and
 366 below 3.8 km (g/m^3). Rad is the radiosonde-derived water vapor density; Opti is the optimized
 367 tomography-derived water vapor density; and Trad is the traditional tomography-derived water
 368 vapor density.

Height		Lower 3.8 km		Upper 3.8 km	
		Bias	RD	Bias	RD
Mean	Rad-Opti	-1.45	-18.76%	0.56	29.87%
	Rad-Trad	-1.88	-24.32%	0.74	39.45%
RMS	Rad-Opti	2.61	33.76%	0.91	48.38%
	Rad-Trad	3.03	38.94%	0.99	52.37%

369 Table 5 provides the statistics values of the differences between GNSS
 370 tomography-obtained and radiosonde-obtained results. As seen from the statistical
 371 results, the RMS and mean values of troposphere tomography using the optimized
 372 technique is less than than that based on the traditional method for altitudes below 3.8
 373 km. In addition, compared with the radiosonde data, the test results show that the
 374 water vapor density quality obtained by the optimized technique is 13.8% better
 375 below 3.8 km and 8.1% better above 3.8 km than that obtained by the traditional
 376 technique.

377 4.2 Quality of GPS tomography technology

378 We also studied the differences in the entire humidity profile between the
 379 tomography-derived and radiosonde-derived results. We used the root mean square
 380 (RMS) and Pearson product-moment correlation coefficient (PCC) as the evaluation
 381 index correlated between the two profiles. PCC is a commonly used measure of the
 382 degree of correlation of two sequences of parameters, and the mathematical model is
 383 as follows (Lee Rodgers and Nicewander, 1988):

$$384 \quad PCC = \frac{\sum_{i=1}^N (X_i - \bar{X}_i)(Y_i - \bar{Y}_i)}{\sqrt{\sum_{i=1}^N (X_i - \bar{X}_i)^2} \cdot \sqrt{\sum_{i=1}^N (Y_i - \bar{Y}_i)^2}} \quad (17)$$

385 Fig. 6 presents the PCC and RMS of tomography results (traditional and optimized)
 386 for August 2016. Here we set up a set of criteria to evaluate the tomography profile
 387 $PCC > 0.90$ and $RMS < 2.0 \text{ g/m}^3$. When GPS tomography results meet these criteria,
 388 they are considered a success. According to the criteria, the success rate of the
 389 inversion is shown in Table 6.

390

391 **Fig. 6.** Time series of PCC and RMS for August 2016. Opti is the optimized tomography-derived
392 water vapor density; and Trad is the traditional tomography-derived water vapor density.

393 **Table 6.** Statistical results of PCC and RMS for August 2016 (%).

	Trad	Opti
PCC	66.29	55.57
RMS	60.14	51.43
PCC and RMS	48.07	38.36

394 As shown in Table 6, the success rate of the optimized technique is nearly 10%
395 higher than that of the traditional technique, and the degree of improvement is evident.
396 In fact, the principles of radiosonde and GPS tomography techniques are different.
397 Radiosonde products reflect the state of the atmosphere at a certain time at the
398 instrument's location, but GPS tomography techniques mirror the average water vapor
399 state. Thus, it is difficult to determine an absolute standard to evaluate the success of
400 GPS tomography results.

401 5. Conclusions

402 In this study, several key techniques in the GNSS tomography method were optimized
403 to improve the accuracy of water vapor density. First, we re-established an
404 atmospheric weighted average temperature model using COSMIC wetPrfs. According
405 to the spatial distributions of water vapor provided by COSMIC products, we used the
406 exponential model to fit the vertical variation of water vapor. The exponential function
407 is usually utilized as the vertical constraint, and we proposed a new method to
408 compute the scale height of water vapor. We determined the smoothing factor of the
409 Gauss distance weighting function using ERA-Interim products. Finally, we used GPS

410 datasets from Hong Kong in August 2016 to compute the PWV and the vertical
411 distribution of water vapor density.

412 To evaluate the quality of the optimized technique, we compared the optimized and
413 traditional technique results with radiosonde-obtained water vapor. The statistical
414 results show that the water vapor density quality obtained by the optimized technique
415 is 13.8% better below 3.8 km and 8.1% better above 3.8 km than that obtained by the
416 traditional technique. We then calculated the success rate of tomographic inversion
417 according to PCC and RMS. The statistics show that the success rate of the optimized
418 technique was approximately 10% higher than that of the traditional technique.
