Abstract

This study developed a model of Total Electron Content (TEC) over the African region. The TEC data were obtained from radio occultation measurements done by the Constellation Observing System for Meteorology, Ionosphere, and Climate (COSMIC) satellites. Data during geomagnetically quiet time ($K_p < 3$ and $Dst > -20$ nT) for the years 2008 - 2011, and 2013 – 2017 were binned according to local time, seasons, solar flux level, geographic longitude and latitude. B splines were fitted to the binned data to obtain model coefficients. The model was validated using actual COSMIC TEC data of the years 2012 and 2018. The validation exercise revealed that, approximation of observed TEC data by our model produces root mean squared error of 5.02 TECU. Moreover, the modeled TEC data correlated highly with the observed TEC data ($r = 0.93$). Due to the extensive input data and the applied modeling technique, we were able to reproduce the well-known TEC features such as local time, seasonal, solar activity cycle, and spatial variations over the African region. Further validation of our model using TEC measured by ionosonde stations over South Africa at Hermanus, Grahamstown and Louisville revealed r values > 0.92 and RMSE < 5.56 TECU. These validation results imply that our model can estimate fairly well TEC that would be measured by ionosondes over locations which do not have the instrument. Another importance of this study is the fact that it has shown the potential of using basis spline functions for modeling ionospheric parameters such as TEC over the entire African region.

1. Introduction

Among the error sources that affect the positioning in Global Navigation Satellite Systems (GNSS) are the propagation medium related errors. In particular, the ionospheric refraction is the largest contributor of the user equivalent range error. This type of frequency dependent error can virtually be eliminated in dual frequency receivers by differential techniques (Hofmann-Wellenhof et al., 2007). For the case of single frequency receivers, some GNSS (e.g Global Positioning System (GPS) and Galileo) broadcast message includes the parameters of an ionospheric model which can be used to compute and correct the ionospheric effects (Guochang, 2007). For instance, the GPS uses the Klobuchar model which represents the zenith delay as a constant value at night and a half cosine function during the day (Klobuchar, 1987). In the framework of the European Galileo constellation, the NeQuick G based on NeQuick model has been proposed to be used for single frequency positioning (see Issue 1.2, September, 2016 of European Commission, titled, European GNSS (Galileo) Open Service - Ionospheric correction algorithm for Galileo single frequency users). The NeQuick and its subsequent modifications (NeQuick G and NeQuick 2) are a three-dimensional, time dependent ionospheric electron density model developed by the Aeronomy and Radio Propagation Laboratory (ARPL) of the Abdus Salam International Center for Theoretical Physics (ICTP) in Trieste, Italy and the Institute for Geophysics, Astrophysics and Meteorology of the University of Graz, Austria (Nava et al., 2008). In addition to using models to reduce ionospheric refraction errors, Space Based Augmentation Systems (SBAS) such as the Wide Area Augmentation System (WAAS), the European Geostationary Navigation Overlay Service (EGNOS), and the GPS-aided Geo Augmented Navigation (GAGAN) are also used (Hofmann-Wellenhof et al., 2007).

For the international standard specification of ionospheric parameters (such as electron density, electron and ion temperatures, and equatorial vertical ion drift), the Committee on Space Research (COSPAR) and the International Union of Radio Science (URSI) recommended the International Reference Ionosphere Model (IRI) (Bilitza, 2001). IRI is an empirical model primarily based on all available experimental data (ground and

1 space based) sources. However, theoretical considerations have been used in bridging
2 data gaps and for internal consistency checks (Bilitza, 2001).

3 The ionospheric Total Electron Content (TEC) is one of the important descriptive
4 physical quantities of the ionosphere (Rama Rao et al., 1997; Ercha et al., 2012). The
5 GNSS measurements obtained from the global and regional networks of
6 International GNSS Service (IGS) ground receivers have become a major source of
7 TEC data. As one of the IGS analysis centers, Center for Orbit Determination in Europe
8 (CODE) provides Global Ionosphere Maps (GIMs) containing vertical TEC data daily
9 using the GNSS data collected from over 200 tracking stations of IGS and other
10 institutions. Several studies have used GIMs from CODE and other IGS analysis
11 centers such as the Jet Propulsion Laboratory (JPL) to construct TEC models (Jakowski
12 et al. 2011a; Mukhtarov et al. 2013; Ercha et al. 2012; Sun et al., 2017). Jakowski et al.
13 (2011a) proposed the Global Neustrelitz TEC Model (NTCM-GL) that describes the
14 average TEC under quiet geomagnetic conditions. The NTCM-GL was developed using
15 GIMs during 1998 - 2007 provided by CODE. A global background TEC model was also
16 built using CODE GIMs by Mukhtarov et al. (2013). The model describes the
17 climatological behavior of the ionosphere. The GIMs from JPL were used by Ercha et al.
18 (2012) to construct a global ionosphere model using Empirical Orthogonal Function
19 (EOF) analysis method. The Taiwan Ionosphere Group for Education and Research
20 constructed a global ionosphere model from GNSS and the Constellation Observing
21 System for Meteorology, Ionosphere, and Climate (COSMIC) GPS radio occultation
22 (RO) observations (Sun et al., 2017). The map of all the averaged Root Mean Squared
23 (RMS) error values of CODE GIMs during the years 2010 - 2012 presented by Najman
24 and Kos (2014) showed high values over low latitude African regions. This could be due
25 to the poor distribution of IGS tracking stations over Africa and inability of the spherical
26 harmonics function used in GIM to describe ionospheric structure over low latitudes.

27 In addition to the existing GIMs discussed in the previous paragraph, regional TEC
28 maps and models have also been constructed. In comparison with the global models,
29 regional TEC models might have better accuracy over the particular region for which it

1 was constructed. Opperman (2008) stated that the higher time and spatial resolution
2 imaging achievable with regional models permits the analysis of localized ionospheric
3 structures and dynamics not observable in global models. Examples of studies that
4 developed TEC models over some parts of Africa are the following. A neural network
5 model of GNSS - vertical TEC (GNSS-VTEC) over Nigeria was developed by Okoh et
6 al., (2016) using all available GNSS data from the Nigerian GNSS Permanent Network
7 (NIGNET). An adjusted spherical harmonic-based TEC model was developed by
8 Opperman, (2008) using a network of South African dual frequency GPS receivers.
9 Habarulema et al. (2011) presented the Southern Africa TEC prediction (SATECP)
10 model that was based on the Neural Network technique. The SATECP generates TEC
11 predictions as function of input parameters, namely, local time, day number of the year,
12 solar and magnetic activity levels, and the geographical location. A neural network
13 based ionospheric model was developed using GPS-TEC data over the East African
14 sector by Tebabal et al. (2019). Recently, Okoh et al. (2019) used neural network
15 technique to develop TEC model over the entire African region. In addition to using TEC
16 obtained by COSMIC RO technique, they used TEC measured by GPS receivers on
17 ground.

18 Due to the lack of a dense network of ground-based GNSS receivers and poor
19 coverage of COSMIC RO data over the African region, the TEC model over the entire
20 African region presented by Okoh et al. (2019) sometimes failed to capture the
21 equatorial ionization anomaly (EIA) over the region. This point has been illustrated with
22 examples in sections 2 and 5. In this study, we applied data binning method to the
23 COSMIC RO TEC data that allowed development of an improved TEC model over the
24 region. Moreover, we demonstrate the potential of the basis spline functions to model
25 TEC over the African region. In section 2, the data and methods of analysis that were
26 used in the study are described. The details of the model proposed in this study are
27 described in section 3. We present comparison between the observed and modeled
28 TEC in section 4. The model validation and the conclusions are presented in sections 5
29 and 6, respectively.

1

2 **2. The Data and methods**

3 **2.1 Data sources**

4 In order to overcome the problem of lack of a dense network of ground based GNSS
5 receivers over the African region, this study used TEC data obtained from RO
6 measurements done by the COSMIC satellites. The integrated electron density
7 (integration being done up to the altitudes of the COSMIC satellites) which is being
8 referred to as TEC in this study can be obtained from ionPrf files which are processed at
9 the COSMIC Data Analysis and Archive Centre (CDAAC)([http://cosmic-
11 io.cosmic.ucar.edu/cdaac/index.html](http://cosmic-
10 io.cosmic.ucar.edu/cdaac/index.html)). The TEC for the individual occultation events
12 were assigned to the geographic coordinates of NmF2 in the same file.

13 In order to obtain integrated electron density approximately up to the altitudes of GPS
14 satellites, Okoh et al., (2019) used neural networks to learn the relationship between
15 coincident TEC measurements done by ground based GPS receivers and COSMIC RO.
16 They showed that the ratio between TEC data from the two sources vary spatially. This
17 observation implies that the neural networks may not learn very well the relationship
18 between TEC measured by ground-based GPS receivers and COSMIC RO over
19 locations which do not have the former data set during the entire study period. As it can
20 be seen in Figure 1 of Okoh et al. (2019), there were large spatial coverages that do not
21 have ground based GPS receivers. Unlike what has been done in Okoh et al. (2019)
22 and Mungufeni et al. (2019) in the current work we used only COSMIC TEC without any
23 adjustments.

24 In this regard, an analysis of coincident ground-based GNSS TEC and TEC from
25 COSMIC occultation data performed by Mungufeni et al. (2019) reveals that the upper
26 quartile of the differences between the two data sets may reach up to ~11 TECU over
27 the northern crest of the Equatorial Ionization Anomaly. Over the southern mid-latitude
28 region, the differences were low (~4 TECU). Since the upper quartiles of the differences
29 can reach up to ~11 TECU, the median/mean values in the worst cases might obviously
30 be much lower than this value. This might be the reason for observing most of the well-

1 known ionospheric TEC features over the African region when the COSMIC RO TEC
2 were appropriately binned as in Mungufeni et al. (2019). Therefore, this study used the
3 TEC obtained from COSMIC occultation measurements to develop TEC model over the
4 African region in order to reproduce these ionospheric features. Such endeavors are
5 important for educational purposes.

6 During geomagnetic storms, the variations in zonal electric fields and composition of the
7 neutral atmosphere contribute significantly to the occurrence of negative and positive
8 ionospheric storm effects in the low latitude region (Rishbeth and Garriot, 1969;
9 Buonsanto, 1999; Adewale et al., 2011). Therefore, since the ionosphere changes in a
10 complex manner during geomagnetic storms, we only considered data on quiet days.
11 The quiet geomagnetic days were identified by examining the 3 hourly Kp and
12 Disturbance storm time (Dst) indices that were obtained from the World Data Center of
13 Kyoto, Japan (<http://swdcwww.kugi.kyoto-u.ac.jp/>). A day was considered to be quiet if
14 all the 8 Kp values in that day were ≤ 3 . In addition to satisfying this condition, the hourly
15 values of Dst in that day should also have values ≥ -20 nT. The two conditions were
16 applied to ensure that both low and mid/sub-auroral latitude geomagnetic disturbances
17 are detected by Dst and Kp indices, respectively. In future, we intend to use TEC data
18 during disturbed geomagnetic conditions to construct a TEC model during
19 geomagnetically disturbed conditions.

20

21 **2.2 Methods of Data Analysis**

22 The TEC data during the years 2008 - 2011 and 2013 - 2017 were used for developing
23 the TEC model over the African region. Due to the adequate data needed to develop
24 an empirical model, we only reserved the data of the years 2012 and 2018 for
25 validation. The period considered in this study represents data of both low and high
26 solar activity level in sunspot cycles 23 and 24. The data within geographic latitude and
27 longitude ranges of $-35 - 35^\circ$ and $-20 - 60^\circ$, respectively, were used to cover the African
28 region. Table 1 presents the number of days per year when there were TEC data over
29 the African region. Since there are many geomagnetically disturbed days in high (2012 -

1 2015) and medium (2011 and 2016) solar activity years, the number of days with data is
2 also reduced in such years compared to low solar activity years (2008 - 2010, 2018).

3 Table 1: Distribution of number of days with data

Year	Number of days with data
2008	219
2009	293
2010	235
2011	174
2012	169
2013	185
2014	164
2015	128
2016	151
2017	154
2018	211

4

5

6 It would be good to bin the TEC data according to geomagnetic latitudes since many
7 structural and dynamical features of the ionized and neutral upper atmosphere are
8 strongly organized by the geomagnetic field (e.g. Emmert et al., 2010). This may be
9 complicated since geomagnetic latitude lines are not usually straight. For convenience
10 and simplicity, we binned the data based on geographic coordinates. In order to
11 observe small scale ionospheric structures, small grid resolutions of 3 and 5 degrees in
12 geographic latitude and longitude, respectively were used to bin the TEC data. These
13 grid resolutions resulted into 24 and 16 latitudinal and longitudinal bins, respectively.
14 Several studies (e.g Krankowski et al., 2011 and Mengist et al., 2019) that have used
15 COSMIC data commonly consider measurements with horizontal smear > 1500 km
16 prone to errors and they reject such measurements. We established that after applying
17 this restriction, there were ~ 40 RO measurements per day during the year 2013 over
18 our study area (not shown here). Based on the previous discussions, this value is far

1 less than the 9,216 (16 longitudinal, 24 latitudinal, and 24 local time) TEC data points
2 required in all grid cells in a day. As stated in section 1, this poor amount of data to
3 represent day of year TEC variation might be the reason for the failure of TEC model
4 presented by Okoh et al. (2019) to capture in some cases the EIA over the African
5 region. Another reason might be the discrepancy which arises due to some locations
6 being represented by adjusted COSMIC RO TEC while others by the ground based
7 GPS TEC data.

8 Since empirical modeling requires adequate data for the mathematical functions to
9 capture the physics inherent in the data, this study did not reject COSMIC RO TEC
10 measurements with horizontal smear > 1500 km. Although not presented here, we
11 observed that the COSMIC TEC data values with smear > 1500 km did not introduce
12 alarming errors. This observation was made when we analyzed COSMIC TEC data
13 which were coincident with TEC observed by ionosonde stations over South Africa (see
14 details in section 5.2) located at Hermanus, Grahamstown, and Louisvale. Interestingly,
15 compared to measurements with horizontal smear > 1500 km, some measurements
16 with horizontal smear < 1500 km were observed to be far from the linear least squares
17 fitting line. Further analysis of COSMIC RO observations over our study area revealed
18 that without restricting horizontal smear, there were ~ 80 RO measurements per day
19 during the year 2013 (not shown here). Still this value is far less than the 9,216 TEC
20 data values required to fill all spatial grid cells in a day. To partially solve this problem,
21 instead of binning data according to year, we binned the data according to different
22 solar flux levels as shown below.

23 For each spatial grid cell, the data were binned at 1-hour interval. TEC values within the
24 bins were averaged to yield 1-hour resolution TEC data over the grids. TEC data for the
25 different days were binned according to F10.7 flux of that day. The F10.7 flux indices
26 were obtained from the Space Weather Prediction Center (SWPC) of the National
27 Oceanic and Space Administration (NOAA) (<http://www.swpc.noaa.gov/>). The F10.7 flux
28 ranges for low solar activity (LSA), medium solar activity (MSA), and high solar activity
29 (HSA) were < 76 , $76 - 108$, and > 108 sfu, respectively. The boundary values 76 and

1 108 sfu of the F10.7 flux ranges correspond to the 75th and 25th percentiles of all F10.7
2 flux values on the days in low (2008 - 2010, 2017 -2018) and high (2012 - 2015) solar
3 activity years, respectively.

4 Table 2: Average monthly F10.7 flux values used in the study

Month	F10.7 flux (sfu)		
	LSA	MSA	HSA
January	71.10	83.94	140.65
February	71.14	87.06	126.23
March	69.81	85.40	130.98
April	71.02	86.09	130.46
May	70.29	90.59	123.80
June	69.51	89.91	118.73
July	68.09	88.14	128.92
August	67.45	85.46	114.53
September	69.20	86.34	122.98
October	70.06	81.88	131.50
November	71.66	82.40	142.95
December	70.82	82.97	142.72

5
6 The data within a specific solar flux bin were further binned based on months of a year.
7 The average of the corresponding F10.7 flux of the days used to represent seasonal
8 TEC were determined and used to capture the variation of TEC with solar flux. Table 2
9 presents the average F10.7 flux values that were determined in the months of a year. In
10 summary, a total of 3,981,312 TEC data values were needed to exist in 16 longitudinal,
11 24 latitudinal, 36 solar flux, 12 monthly, and 24 hourly bins, in order to determine the
12 model coefficients. However, from the data of the entire study period, only 121,447 bins

1 were filled with TEC data values. The remaining bins were filled by estimation following
2 the procedures described in 3 steps below.

3 1. At a particular spatial grid cell, the diurnal TEC was divided into two local time
4 sectors, namely, (i) 10:00 – 24:00 LT, and (ii) 0:00 – 10:00 LT. Sector (i) which is
5 day time and before mid-night includes the time when daily and secondary TEC
6 peaks are expected, while (ii) which is mostly at night is when TEC varies slowly.
7 We need to mention that spline functions (De-Boor, 1978) were used to estimate
8 missing TEC values. When slow variation of TEC was expected as in sector (ii),
9 estimations were done when there were at least a few (>2) TEC data available.
10 In cases where rapid TEC variations are expected as in sector (i), estimations of
11 missing values were done when at least half of the total expected number of data
12 points were filled with TEC data. For example, when there were at least 4
13 measurements in sector (ii) the missing values were obtained by evaluating a
14 spline function fitted through the existing TEC data values. On the other hand,
15 when there were at least 7 (half the number of hours during 10:00 – 24 LT) TEC
16 values in sector (i), the missing values were obtained by evaluating a spline
17 function fitted to the available data values. After estimating the missing TEC data
18 from the two sections of the diurnal TEC, the entire diurnal TEC data over a
19 particular grid cell was then considered to estimate the missing values. When
20 there were at least 12 (half the number of hours in a day) values, the missing
21 values were obtained by evaluating a spline function fitted to the existing data
22 values.

23 2. At a particular latitude and local time, the values of TEC along all the longitudes
24 were divided into western (-20 – 20° E) and eastern (20 – 60° E) longitude
25 sectors. Each of the longitude sectors contained 8 bins. At night, when there
26 were at least 3 TEC values over any longitude sector, the missing values were
27 obtained by evaluating spline function fitted to the available data points, while
28 during the day, when there were at least 4 Tec values, the missing values were
29 obtained by evaluating a spline function fitted to the available data points. After

1 estimating the missing TEC values over the two longitude sectors, the TEC over
 2 all longitudes were then considered to estimate the missing values. At night,
 3 when there were at least 8 values, the remaining values were obtained by
 4 evaluating a spline fitted to the available TEC data points. The missing values
 5 during day time, were estimated when there were at least 10 measurements
 6 available.

- 7 3. Procedure 3 is similar to 2, except for variations of TEC as a function of latitude
 8 were considered at specific values of longitude and time. TEC values over the
 9 latitudes were divided into lower (-35 – 0° S) and upper (0 – 35° N) latitudinal
 10 sectors. There were 12 bins in each of the latitudinal sector. To estimate missing
 11 TEC values at night over a latitudinal sector, at least 4 measurements were
 12 required to be available, while during the day, at least 6 values were required.
 13 When TEC data over the combined latitudinal sectors were considered to
 14 estimate the missing values, at least 12 values were required to be available.

15 After repeating procedures 1 – 3 three times, all the 3,981,312 bins were filled with TEC
 16 data and they were used to obtain the model coefficients as explained in section 3.

18 3. The Model

19 The TEC over the African region was expressed as

$$20 \text{TEC}(t, d, F, \lambda, \phi) = \sum_{i=1}^{24} \sum_{j=1}^{12} \sum_{k=1}^{36} \sum_{l=1}^{16} \sum_{m=1}^{24} a_{ijklm} \times N_i(t) \times N_j(d) \times N_k(F) \times N_l(\lambda) \times N_m(\phi) \quad (1)$$

21 where the linear model coefficients a_{ijklm} were determined by the least square fitting
 22 procedure to the 3,981,312 TEC data values as in Abdu et al. (2003); Jakowski et al.
 23 (2011b); Mungufeni et al. (2015). In Equation 1, $N_i(t)$, $N_j(d)$, $N_k(F)$, $N_l(\lambda)$, and $N_m(\phi)$ are
 24 B splines of different orders to represent variations of TEC with local time, seasons,
 25 solar flux level, longitude, and latitude respectively. Most of the B splines were of
 26 order 2, except for those used to represent LT and latitudinal variations which were of
 27 order 4. The order of splines used to represent LT and latitude was higher to cater for

1 the rapid variations of TEC with these two parameters. Twenty-four local time nodes 1,
2 2, ..., 24 were used. For simple interpolation between months, seasonal/monthly
3 nodes were placed at the 15th day of each month. Solar flux nodes used in the various
4 months are as shown in Table 2. The longitudinal nodes were separated by 5° and
5 placed at longitudes $-17.5, 12.5, 7.5, \dots, 57.5$ degrees, while the latitudinal nodes were
6 separated by 3° and placed at latitudes $-34.5, -31.5, -28.5, \dots, 34.5$ degrees.

7

8 **4. Comparison of Observed and Modeled TEC**

9

10 In order to assess the ability of the model to describe the data used to construct it,
11 modelled data were compared with the binned data that were used to solve equation 1.
12 The results of the self-consistency check are presented in Figure 1. It is important to
13 note that validation using data that was not included during modeling is provided in
14 section 5. Panels in column (i) of Figure 1 present the observed binned TEC data while
15 column (ii) presents the corresponding modeled TEC data. In column (iii), we present
16 the differences between the observed and modeled TEC data, referred to as errors. In
17 Figure 1, rows (a), (b), and (c) correspond to LSA, MSA, and HSA, respectively. The
18 horizontal magenta lines in Figure 1 and later also in Figure 2 indicate the location of
19 $\sim 0^\circ$ dip latitude on the corresponding panel. As expected, Figure 1 clearly shows that
20 the corresponding modeled TEC almost perfectly matches the observed binned TEC.
21 This can be confirmed by the small (<0.1 TECU) error values presented in panels of
22 column (iii). The variations of the ionosphere with local time, solar flux level as well as
23 location that are exhibited in Figure 1 gives the confidence of relying on the binned data
24 as a good representation of the ionosphere. The physical explanations for these
25 variations are as follows. The increase of both observed and modeled TEC that occurs
26 when solar flux level increases is usually attributed to increased ionizing radiations in X-
27 ray and Extreme Ultra-Violet (EUV) bands, which in turn leads to increased TEC in the
28 ionosphere (Hargreaves, 1992).

29

1
 2 Figure 1. Variation of TEC as a function of geographic latitude and local time in March
 3 equinox at 37.5° E. Panels in rows (a) - (c) correspond to LSA, MSA, and HSA,
 4 respectively, while panels in columns (i) - (iii) correspond to observed binned, modeled
 5 TEC, and difference panels between observed and modeled TEC (errors), respectively.
 6 Magenta line indicates $\sim 0^\circ$ dip latitude.

7
 8 The diurnal variation of TEC matches very well with the variation of photo-ionising
 9 radiations. At sunrise, the electron density begins to increase rapidly owing to photo-
 10 ionization (Schunk and Nagy, 2009). After this initial increase at sunrise, electron
 11 density displays a slow rise throughout the day, and then it decays at sunset as the
 12 photo-ionization source disappears. Another diurnal feature of variation of TEC
 13 exhibited in Figure 1 is the existence of a secondary maximum of TEC. This can clearly
 14 be seen in panels of row (c) along the magenta lines, where the first peak occurs at
 15 $\sim 15:00$ LT and the second at $\sim 18:00$ LT. The formation of a secondary maximum of
 16 TEC that was mentioned previously may be explained as follows. During the day, the
 17 thermospheric wind generates a dynamo electric field in the lower ionosphere that is
 18 eastward (Schunk and Nagy, 2009). The eastward electric field, E in combination with

1 the northward geomagnetic field, B produces an upward $E \times B$ drift of the F region
2 plasma. As the ionosphere co-rotates with the Earth toward dusk, the zonal (eastward)
3 component of the neutral wind increases. The increased eastward wind component, in
4 combination with the sharp day-night conductivity gradient across the terminator leads
5 to the pre-reversal enhancement in the eastward electric field (Batista et al., 1986;
6 Schunk and Nagy, 2009). The F layer therefore rises as the ionosphere co-rotates into
7 darkness. Although in the absence of sunlight after sunset, the lower ionosphere rapidly
8 decays, there exists high electron density at high altitudes, yielding the secondary
9 maximum in TEC.

10

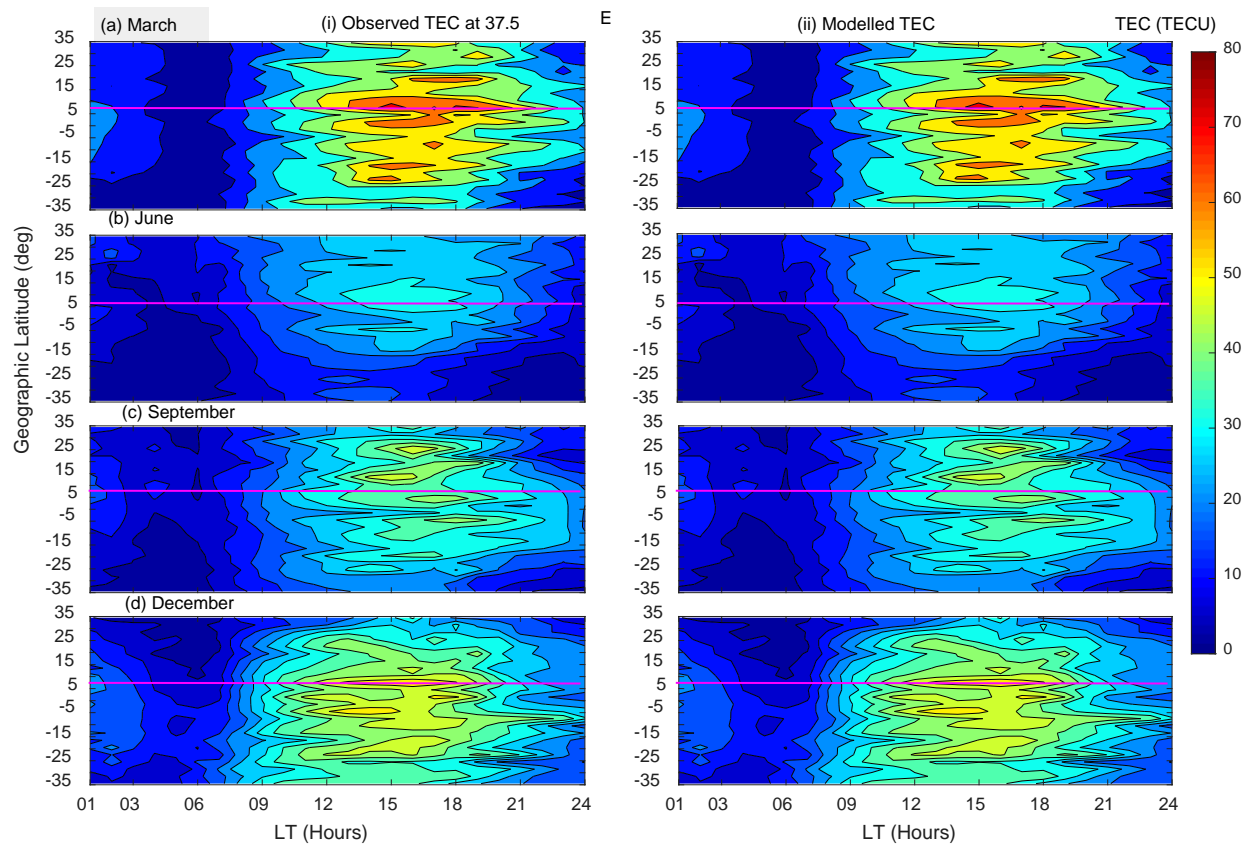

11 Panels in rows (b) and (c) of Figure 1 demonstrate the existence of the EIA region,
12 where there exist two belts of high electron density on both sides of 0° dip latitude. The
13 EIA is usually attributed to the upward $E \times B$ drift which lifts plasma to higher altitudes.
14 The plasma then diffuses north and south along magnetic field lines. Due to gravity and
15 pressure gradient forces, there is also a downward diffusion of plasma. The net effect is
16 the formation of the EIA region (Appleton, 1946). Another feature of EIA that can be
17 seen on panels in rows (b) and (c) of Figure 1 is the asymmetry of the crests. Along
18 120° longitude sector Zhang et al. (2009) reported the asymmetry of EIA crests. As
19 described later at the end of this section, the direction of neutral meridional winds in
20 March may favour high values of electron density over the southern crest.

21

22 Generally, Figure 1 shows that, the locations outside the EIA region have lower TEC
23 values compared to locations around and within the EIA region. The low values of TEC
24 over locations outside the EIA region might be due to lower elevation angle of solar
25 radiation flux which is responsible for creation of electrons (Schunk and Nagy, 2009).
26 The solar radiation flux is usually low for locations far from the sub-solar point. The latter
27 situation is dominant over locations outside the EIA region, especially in March. The
28 closeness of the sub-solar point to the locations within the EIA regions result into high
29 solar radiations over these locations. As a result, high TEC values were observed over
30 locations within the EIA region.

To demonstrate that the modeled TEC captures TEC variation with seasons, we present Figure 2. In the figure, columns (i) and (ii) present observed binned and the corresponding modeled TEC respectively. Moreover, rows (a) - (d) present TEC data during March, June, September and December, respectively.

7

8 Figure 2. Variation of TEC as a function of latitude and local time in HSA at 37.5°E.
9 Panels in rows (a) - (d) are for March equinox, June solstice, September equinox, and
10 December solstice respectively, while panels in columns (i) and (ii) are observed binned
11 and modeled TEC respectively. Magenta line indicates 0° dip latitude.

12

13 As already observed in Figure 1, it can clearly be seen from Figure 2 that the modeled
14 TEC almost perfectly matches the observed TEC data. Among the many features of
15 TEC exhibited by both observed and modeled TEC data, we would like to emphasize
16 the (i) equinoxial asymmetry of TEC, (ii) occurrence of lowest TEC in June solstice, and

1 (iii) high values of TEC in December. Features (ii) and (iii) were recently reported based
2 on a similar data by Mungufeni et al. (2019). The reader may refer to this study for more
3 discussions. Mungufeni et al. (2016a) observed equinoxial asymmetry when studying
4 ionospheric irregularities over the African low latitude region. They observed over the
5 East African region that, the irregularity strength in March equinox was higher than that
6 in September equinox. They attributed the equinoxial asymmetry to meridional winds in
7 March which might blow northward. Such a direction would lift plasma up where
8 recombination is not common. On the other hand, in September, the winds might blow
9 southward. This could lead to recombination at low altitudes.

10

11 **5. Model Validation**

12 **5.1 Validation using reserved COSMIC RO TEC**

13 In addition to comparing observed binned TEC with the corresponding modeled TEC,
14 we validated our model using observed TEC in the years 2012 and 2018. The data
15 during these two years were not used in developing the model. The TEC data in
16 the years 2012 and 2018 were binned according to local time and spatially in a similar
17 manner to that mentioned in subsection 2.2. The corresponding local time, day of the
18 year, solar flux, and spatial coordinates of the data were noted and then used to
19 generate the corresponding modeled TEC. Figure 3 presents a scatter plot showing the
20 observed TEC against the corresponding modeled TEC. The red line in the figure
21 indicates linear least squares fit to the data in the panel. Furthermore, indicated in
22 Figure 3 are: (i) the correlation coefficients, r , (ii) the r squared values, (iii) the number of
23 data points, n plotted and (iv) the root mean squared error, RMSE when the modeled
24 TEC is used to represent the observed TEC.

1

2 Figure 3. Scatter plot of observed TEC against modeled TEC.

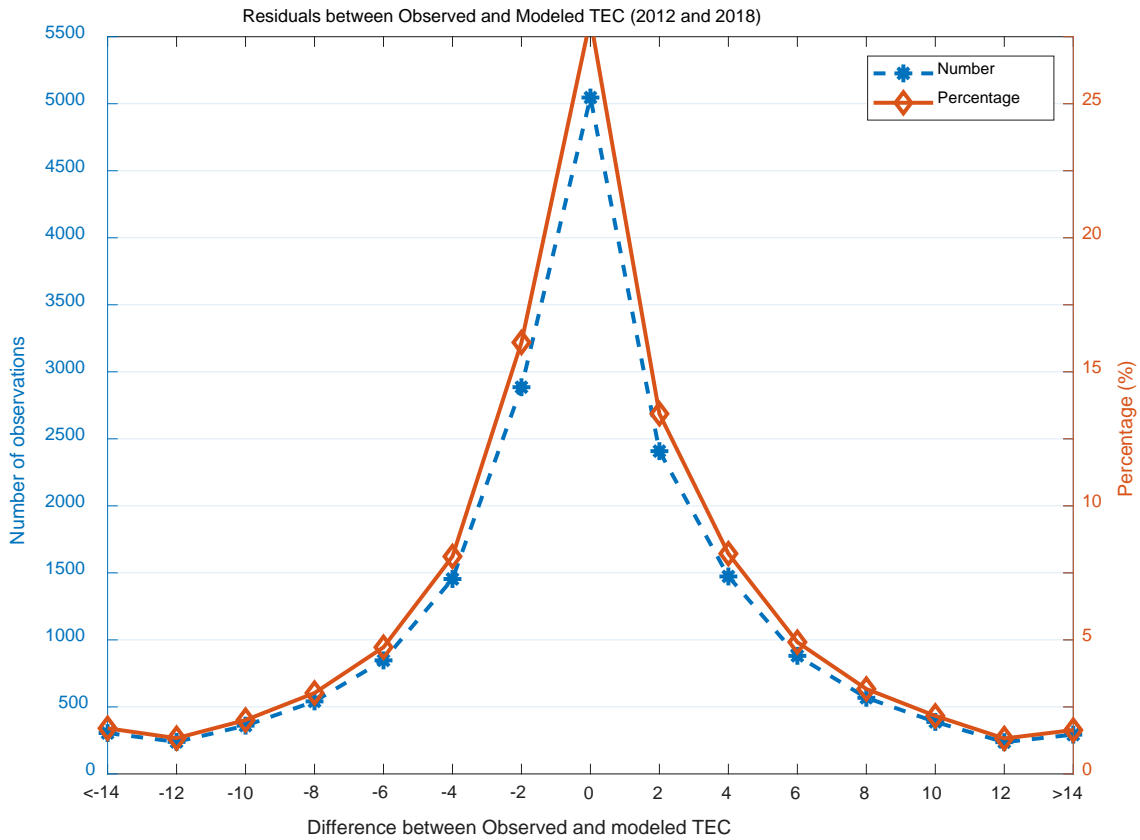

3

4 The following observations can be noted from Figure 3. (i) The modeled TEC correlates
5 highly ($r \sim 0.93$) with the observed TEC. (ii) The r squared values indicate that high
6 proportions ($\sim 87\%$) of the variations in the observed TEC can be predicted
7 by the modeled TEC. (iii) The RMSE value of 5.05 TECU signify that the modeled TEC
8 closely approximates the observed TEC.

9 In order to show that the observed and modeled TEC have similar magnitudes in
10 addition to their similar variation depicted in Figure 3, we computed the differences
11 between corresponding values of the data plotted in the figure. These were referred to
12 as errors. We also computed the percentage of the different errors. The left and right
13 hand vertical axis in Figure 4 present the distribution of the number of observed errors
14 and their percentages, respectively. It can be seen from the figure, the errors are

1 randomly distributed since the distribution curve is symmetric about 0 TECU. Indeed,
2 the magnitudes of the modeled TEC values are close to that of the observed TEC since
3 the majority of the error values are close to zero.

4

5

6 Figure 4. The blue and red curves show the distribution of the number of observed
7 errors (difference between observed and modeled TEC) and the percentage of the
8 errors, respectively. The cases of high error values (> 10 TECU) as seen on the right-
9 hand side vertical axis mostly have < 2.5 % occurrence probability.

10

11

12

13

14

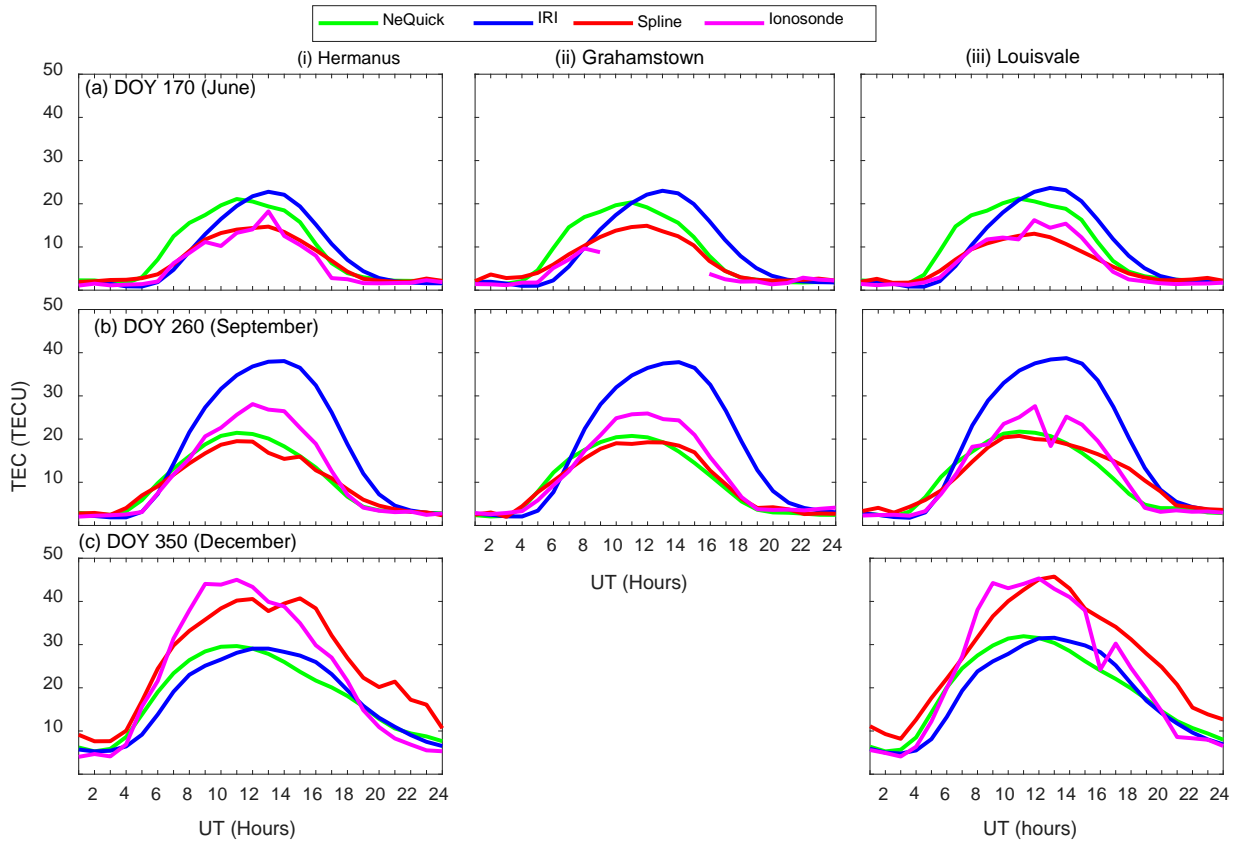

15

5.2 Validation using ionosonde TEC measurements

The TEC data measured by the digisonde ionosonde stations over South Africa located at Hermanus, Grahamstown and Louisvale can be accessed from the National Oceanic and Atmospheric Administration (NOAA) website via the link, <ftp://ftp.ngdc.noaa.gov>. The data obtained from the NOAA website is in form of auto-scaled ionospheric parameters such as peak height in F2 layer, critical frequency in F2 layer, and TEC which are stored in Standard Archiving Output (SAO) format files. It should be noted that the TEC data provided in SAO files are obtained by integrating electron density profiles up to altitude of ~700 km. More details about the auto-scaling program (real-time ionogram scaler with true height (ARTIST)) and the electron density profiles they produce can be found in Reinisch and Huang (2001) and Klipp et al. (2020).

Figure 5 presents with magenta lines the diurnal patterns of TEC measured by ionosonde stations at Hermanus (panels in column (i)), Grahamstown (panels in column (ii)) and Louisvale (panels in column (iii)). The corresponding TEC generated by our spline technique model (spline), Nequick 2, and IRI-2016 are superimposed with red, green and blue lines, respectively. We need to mention that during computation of TEC using NeQuick 2 and IRI-2016, the height was limited to the approximate altitude of the COSMIC satellites (800 km). The panels in rows (a) - (c) show TEC on day of year 170 (June), 260 (September), and 350 (December), respectively. All these three days of the year 2013 were geomagnetically quiet. Preliminarily, Figure 5 appears to reveal that IRI-2016 either overestimates (December) or underestimates (June and September) the TEC measured by the ionosonde stations. On the other hand, our spline model and NeQuick 2 seem to depict good correspondence between the observed and the modeled TEC. It can also be seen from Figure 5 that over a particular station, the shape of curves on different days representing TEC generated by the IRI-2016 and NeQuick 2 models are similar. This is expected since these two models were meant to reproduce monthly median values of the ionosphere. This means that our model, based on spline functions may capture better the day-to-day variability of the ionosphere.

5
6
7
8
9

Figure 5: Magenta color shows diurnal TEC observed by ionosonde stations at Harmanus (panels in column (i)), Grahamstown (Panels in column (ii)), and Louisvale (Panels in column (iii)). The green, blue, and red colors show TEC estimations using NeQuick 2, IRI-2016 and Spline models, respectively. Panels in rows (a) - (c) show diurnal TEC during the year 2013 on DOY 170, 260, and 350, respectively.

10 We generated such data plotted in Figure 5 for geomagnetically quiet days of the entire
11 year 2013 and then performed statistical analysis of the observed and the model TEC
12 data. Table 3 presents in columns 3 the correlation coefficients, r for the correlations
13 between modeled and ionosonde TEC. Moreover, the table presents the RMSE when
14 the ionosonde TEC was estimated using the models listed in column 2. The number of
15 observations, n over each station that were used to determine, r and RMSE are put in
16 brackets below the station name.

9
10
11
12
13
14
15
16
17

Table 3: Correlation coefficients, r and RMSE associated with estimation of TEC observed by ionosonde stations using models

Ionosonde Station /number of observations	Model	r	RMSE (TECU)
Hermanus (n = 5,110)	Spline	0.92	4.64
	IRI-2016	0.86	5.45
	NeQuick 2	0.92	4.10
Grahamstown (n = 4,450)	Spline	0.88	5.56
	IRI-2016	0.82	6.29
	NeQuick 2	0.86	5.27
Louisville (n = 4,543)	Spline	0.94	3.82
	IRI-2016	0.87	5.62
	NeQuick 2	0.94	3.73

It can be seen from Table 3 that the r values associated with NeQuick 2 and spline based model are consistently better when compared with that of IRI-2016. Moreover, the RMSE values associated with IRI-2016 are the highest in all the cases. These two observations indicate that compared to spline and NeQuick 2, IRI-2016 poorly estimates TEC at the locations of the ionosondes. The RMSE values associated with NeQuick 2 are always slightly lower than that of spline, while the r values associated with spline are mostly comparable or slightly higher than that of NeQuick 2. These discussions demonstrate that our spline model generates TEC values consistently with that observed by ionosondes. This implies that equivalent TEC measured by ionosondes over locations which do not have ionosonde stations can be predicted fairly well using our model.

1 **5.3 Comparison of our model with existing regional models**

2 It would be good to compare error levels produced when some measured TEC are
3 compared with modeled TEC generated by (i) the existing regional TEC models
4 discussed in section 1 and (ii) our spline technique TEC model. We may not perform
5 such analysis since models in (i) are based on electron density integrated from ground
6 up to GPS satellites (~20,200 km), while model in (ii) is based on electron density
7 integrated up to ~800 km. However, we present Figures 6 and 7 to compare EIA
8 features captured by our spline technique model and the neural networks technique of
9 Okoh et al. (2019). The TEC plots based on the neural networks technique can be
10 obtained from MATLAB Central website (Okoh et al., 2019)
11 ([https://www.mathworks.com/matlabcentral/fileexchange/69257-african-gnss-tec-afritec-](https://www.mathworks.com/matlabcentral/fileexchange/69257-african-gnss-tec-afritec-model?s_tid=prof_contriblnk)
12 [model?s_tid=prof_contriblnk](https://www.mathworks.com/matlabcentral/fileexchange/69257-african-gnss-tec-afritec-model?s_tid=prof_contriblnk)). We present in Figure 6 examples of TEC generated by
13 neural network model during the year 2012 at 11:00 UT. Over the East African sector
14 (LT = UT + 3), this time translates to 14:00 LT and falls within the range of LT when EIA
15 exists over the region (Mungufeni et al., 2018). Panels (a) and (b) in Figure 6 present
16 TEC during March (DOY 81) and September (DOY 260) equinoxes, respectively, while
17 (c) and (d) present during June (DOY 171) and December (DOY 347) solstices,
18 respectively. It is important to mention that these 4 days were geomagnetically quiet.

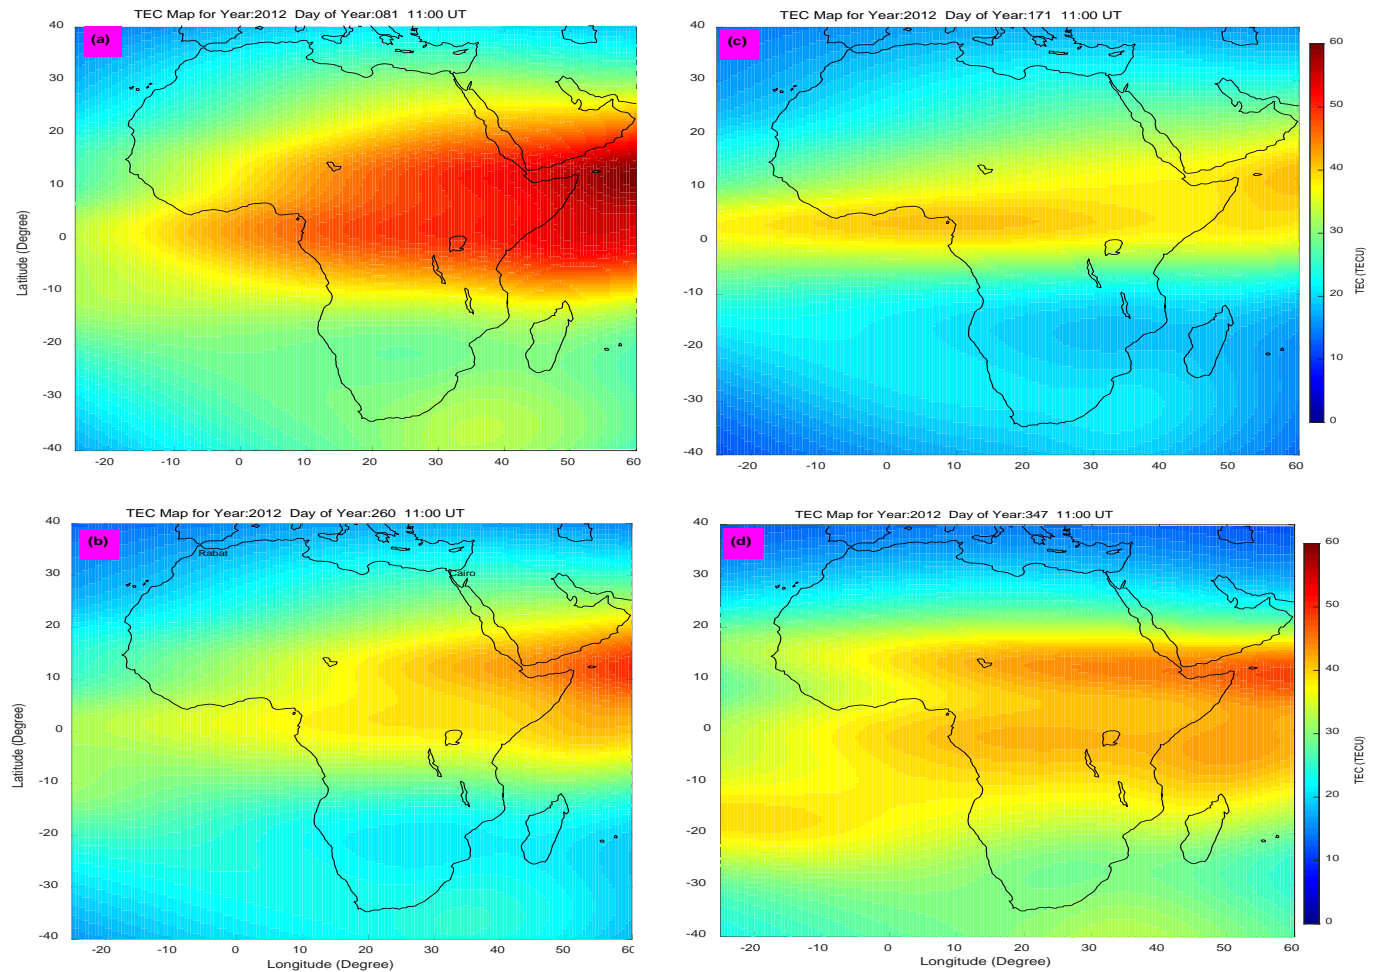

19

20

21

22

23

1
 2 Figure 6: Neural Network TEC maps during the year 2012 at 11:00 UT. Panels (a) and
 3 (b) are for March (DOY 81) and September (DOY 260) equinoxes, respectively, while
 4 (c) and (d) are for June (DOY 171) and December (DOY 347) solstices, respectively.

5
 6 In order to generate TEC maps using our model for purposes of comparing with TEC
 7 maps in Figure 6, we noted and used the F10.7 flux values on the days indicated in the
 8 figure. The TEC maps generated using our model that correspond to TEC maps
 9 presented in Figure 6 are presented in Figure 7.

1
 2 Figure 7: Similar to Figure 6, but generated by spline modeling technique. Magenta
 3 arrows indicate approximate locations of EIA trough.

4 Unlike our TEC maps in Figure 7 which clearly show the EIA trough (see magenta
 5 arrows) in all the seasons, the neural network technique TEC maps (Okoh et al., 2019)
 6 of Figure 6 only clearly capture the EIA trough in December solstice. As pointed before,
 7 this short fall in neural network TEC model might be due to poor amount of data to
 8 represent day of year during model development. Another observation that can be
 9 made from Figures 6 and 7 is that unlike the neural network model which yields smooth
 10 spatial TEC variation, the spline modeling technique does not yield smooth spatial TEC
 11 variation. In real life, measurement or observed values rarely vary smoothly. Since the

1 spline modeling technique produces results (see Figure 1) which demonstrate that the
2 modeled data matches almost perfectly the observed data, it is expected that the spatial
3 variations of TEC in maps of Figure 7 are not smooth.

4

5 **6. Conclusions**

6

7 This study developed a model of TEC measured by COSMIC satellites. The TEC data
8 were binned according to local time, seasons, solar flux level and spatially. The
9 coefficients of B splines that were fitted to the binned data were determined
10 by means of the least square procedure. As expected, the modeled TEC almost
11 perfectly matched the corresponding observed binned TEC data. The model was
12 validated with independent data that were not used in the model development. The
13 validation revealed that (i) the observed and the modeled TEC correlate highly ($r = 0.93$),
14 (ii) the coefficient of determination R^2 which is the proportion of variance in the observed
15 data predicted by our model was 87 %, and (iii) the modeled TEC closely approximates
16 the observed TEC (RMSE of 5.02 TECU). Due to the extensive input data and the
17 applied modeling technique, we were able to reproduce the well-known features of TEC
18 variation over the African region. Further validation of our model using TEC obtained
19 from ionosonde stations over South Africa at Hermanus, Grahamstown and Louisville
20 reported r values > 0.92 and $RMSE < 5.56$ TECU. These validation results imply that
21 our model can estimate fairly well TEC that would be measured by ionosondes over
22 locations which do not have the instrument.

23

24 **Acknowledgments**

25 This study received financial support from research number, 018-1370-20 in the
26 department of Astronomy and Space Science of Chungnam National University which
27 was awarded by the Air Force Research Laboratory of the United States of America.
28 The first author, Patrick Mungufeni greatly appreciates the immense contribution of Prof.

1 Claudia Stolle towards shaping the presentation of the manuscript. We
2 thank the developers of the IRI and NeQuick models for making their models available.
3 Dst data is provided by the World Data Center for Geomagnetism at Kyoto
4 (<http://swdcwww.kugi.kyoto-u.ac.jp/>). Kp data is provided by GFZ Potsdam, [ftp://ftp.gfz-](ftp://ftp.gfz-potsdam.de/pub/home/obs/kp-ap/)
5 [potsdam.de/pub/home/obs/kp-ap/](ftp://ftp.gfz-potsdam.de/pub/home/obs/kp-ap/). F10.7 flux data was obtained from
6 <http://www.swpc.noaa.gov/>, while ionPrf files used to derive COSMIC TEC were
7 obtained from <http://cosmic-io.cosmic.ucar.edu/cdaac/index.html>. We thank NOAA for
8 availing ionosonde data via the link, <ftp://ftp.ngdc.noaa.gov>.
