

# Historical Aurora Borealis Observations in medieval Anatolia (AD 1-1453): Implications for the past solar activity

Nafiz MADEN<sup>a,1</sup>

<sup>a</sup> Department of Geophysics, Gümüşhane University, TR-29100 Gümüşhane, Turkey

**Abstract:** In this paper, it is reviewed the relationships between the aurora observations, past solar activity and climatic change in Anatolia during medieval period. This purpose, it is presented two historical aurora catalogs for Anatolia and Middle East regions at various dates by using historical texts, chronicles and other auroral records. Available catalogs in literature are covered records observed in the Europe, Japan, Russia and Middle East. There is no study dealing only with the historical aurora observations recorded in Anatolia. The data of the catalog support that there is a considerable relationship between the aurora activity and past strong solar activity. High aurora activity during the years around 1100 in Anatolia and Middle East is quite consistent with the past solar variability and planetary climatic changes drastically affecting on the economy and human events.

**Keywords:** Historical aurora records; Solar activity; Climatic changes; Anatolia.

23        **1. Introduction**

24        A number of researchers presented the low and middle-latitude aurora catalogs  
25 (Table 1) from Europe (Mairan, 1733; Frobessius 1739; Fritz, 1873; Schove, 1948; Link,  
26 1962; Dall'Olmo, 1979; Stothers, 1979; Krivsky and Pejml, 1988; Vaquero et al., 2010;  
27 Scafetta and Willson, 2013), Arabic countries (Basurah, 2006), Japan (Matsushita, 1956;  
28 Nakazawa et al., 2004; Kataoka et al., 2017), and China (Schove and Ho, 1959;  
29 Keimatsu, 1976; Hayakawa et al., 2015; Kataoka and Iwashashi, 2017). Aurorae are the  
30 most majestic luminous phenomenon observed in the sky. The aurora observations were  
31 described as "sign", "a fiery shining sign", "a very fabulous sign", "red sky", "a fiery red  
32 sky", "sky fire", "a great fire", "a fiery cloud", "a frightful and strange omen", "a fire-like  
33 omen", "a bloody spear light", "blaze of light", "a sunlight light". The form of aurorae was  
34 defined as "luminous column".

35        The historical aurora catalogs have been used to recognize the past solar activities  
36 (Siscoe, 1980; Silverman, 1992; Schröder, 1992; Schröder 1994; Basurah, 2006;  
37 Vazquez et al., 2006; Hayakawa et al., 2015), Earth's climate change (Pang and Yau,  
38 2002; Schröder, 2004; Gallet et al., 2005; Bard and Frank, 2006; Scafetta, 2012) and  
39 perception of human civilizations (Schröder, 2004; Gallet et al., 2006; Silverman, 2006).  
40 The state of the geomagnetic field and the form of magnetosphere extremely control the  
41 location of auroral zone (Korte and Stulze, 2016). The visibility of the aurorae at low  
42 latitudes is very scarce and closely connected with the strong geomagnetic storms related  
43 to the high-speed solar wind or interplanetary transients (Eather, 1980; Basurah, 2006;  
44 Vazquez et al., 2006).

45        Mairan (1733) presented that the first scientific monography covers a list of 229  
46 historical aurorae during the period of 502-1731. In 1852, Wolf noticed that the aurorae

47 match with periods of high sunspot number, according to the historical aurora catalog  
48 including more than 6300 records (Wolf, 1857). Fritz (1873), who listed 77 European  
49 Aurora records during 1707-1708, published the historical auroral catalog and separated  
50 auroral sightings into five categories based on the latitude and longitude (Schröder, 1994).  
51 Link (1962) published a useful aurora catalog seen in European countries based on eight  
52 previous catalogs compiled by Frobessius (1739), Mairan (1754), Schoning (1760), Boué  
53 (1856), Wolf (1857), Lovering (1868), Fritz (1873) and Seydl (1954).

54 Vaquero et al. (2010) declared a set of auroral observation of Francisco Salva  
55 Campillo who recorded in Barcelona during 1780-1825. This catalog represents a sudden  
56 drop in the number of annual auroral observations at about 1793 owing to the secular  
57 minimum in solar activity (Vaquero et al., 2010). Scafetta and Willson (2013) studied the  
58 historical Hungarian auroral records covering 438 years. They found that the maxima of  
59 the auroral observations comply with the maxima in the sunspot records and there is a  
60 positive correlation amidst the auroral records, the solar and climate activities.

61 Neuhäuser and Neuhäuser (2015) are implemented five criteria of likeliness for  
62 aurora catalogs as night-time (darkness, sunset, sunrise), non-southern directions  
63 (northern, NE, NW, E-W, W-E), color (red, reddish, fiery, bloody, green, black), dynamics  
64 (fire, fiery), and repetition. One could decide whether an observation is aurorae by  
65 considering its color, brightness, dynamics, duration, geomagnetic latitude. The  
66 observation is classified as potential (N=0), possible (N=1), very possible (N=2), probable  
67 (N=3), very probable (N=4), or certain (N=5) according to the criteria number (N) satisfied  
68 (Neuhäuser and Neuhäuser, 2015). However, Stephenson et al. (2019) showed that these  
69 criteria may be adequate for normal aurorae, which cannot be classified as extreme  
70 events associated with extreme magnetic storms. Korte and Stolze (2016) showed that

71 the intensity and tilt of the geomagnetic field and high solar activity are closely related to  
72 the Aurora occurrence.

73 The available catalogs described above present a number of records covering  
74 Europe, Japan, China, Russia and Middle East. There is no study dealing only with the  
75 historical aurora observations recorded in Anatolia. Anatolia have not been studied until  
76 now with respect to historical-climatological data and aurora observations. The goal of this  
77 study is to compile a historical Anatolian Aurora catalog (hAAC) during medieval period  
78 by scanning the available sources and catalogs in literature. The catalog could be used to  
79 analyze the past solar activity and earth climatic changes impacting on the economy and  
80 human events. This research may also contribute to the understanding of public  
81 perception of the historical auroras.

82

83 **2. Historical Anatolian Aurora Catalog (hAAC) through medieval period**

84 It is propounded a historical aurora catalog observed only in Anatolia during  
85 medieval period collected from Link (1962), Botley (1964), Baldwin (1969), Newton  
86 (1972), Stothers (1979), Eather (1980), Melissinos, (1980), Silverman (1998), Dall'Olmo  
87 (1979), Andreasyan (2000), Little (2007), Silverman (2006), Neuhäuser and Neuhäuser  
88 (2015) resources. In this catalogue, 23 different historical aurora records observed in  
89 Anatolia are presented during medieval period in Table 2. The location map of the  
90 historical Anatolian observations is given in Figure 1. A number of Anatolian aurora  
91 observations are summarized in Table 3. Another collected ancient aurora catalog  
92 consisting 45 auroral observations is shown in Table 4 for the Middle East region during  
93 the same period using Islamic historical texts, Arabic chronicles and other auroral records  
94 given in Table 1. These two catalogues are plotted in Figure 2 and evaluated altogether.

95 The historical Anatolian and Middle East aurora records overlap through medieval period  
96 especially between 1097 and 1129 years (Fig. 3). Also, Chinese and European aurora  
97 observations are in harmony with each other in this period (Siscoe, 1980).

98 In Anatolia, the first auroral observation was done in Constantinople at 333  
99 (Stothers, 1979). Stothers (1979) described these observations as a sky fire according to  
100 the works of Aurelius Victor (320-390), who was a historian and politician of the Roman  
101 Empire. On the other hand, Eather (1980) described an Aurora observation over  
102 Constantinople at about 360 BC during the siege on Byzantium by Philip of Macedonia.

103 Little (2007) described an aurora observation record in Constantinople at 396: "A  
104 fiery cloud was observed from the East while the city darkened. At first, it was small, but  
105 later gradually grew and moved towards the city. At last, it terribly enlarged and poised  
106 over the entire city. A terrifying flame appeared to hang down. All people stacked to the  
107 church, and the place could not receive huge mass".

108 According to the Link (1962) and Hayakawa et al., 2017, an aurora appeared in  
109 Asia Minor on 22 August 502, Thursday. This aurora was also observed both in Edessa  
110 (Botley, 1964) and Palestine after an earthquake (Russell, 1985) based on to the  
111 Chronicle of Joshua the Stylite and Chronicle of Zuqnin. Joshua the Stylite described it:  
112 "On the 22rd of August this year, on the night preceding Friday, a great fire appeared to  
113 us blazing in the northern quarter the all night. It was believed that the whole earth was  
114 going to be devastated that night by a fire storm. However, the mercy of our Lord  
115 preserved us without damage". This appearance of the aurora borealis was also reported  
116 in Chronicon Edessenum without apocalyptic detail (Trombley and Watt, 2000).

117 According to the Historia Ecclesiastica of Ptolomaeus Lucensis there was an  
118 aurora sighting at a night of 633 in Constantinople (Dall'Olmo, 1979): "A bloody sign

119 appearing just at that time was sighted. A bloodstained spear and a sharp light were  
120 observed on the sky for nearly all night". Theophanes (758/760-817), a Byzantine monk,  
121 theologian, and chronicler, reported an observation in 667 winter: "There was a sign which  
122 appeared in the sky in the same winter". Theophanes reported another observation in  
123 675-676: "This year a sign was seen in the sky on a Sabbath day" (Turtledove, 1982).

124 Theophanes recorded three aurora events for 734, 743 June and 744 in  
125 Constantinople. The first aurora observation was reported in 734: "A fiery sign shining like  
126 a burning brand appeared in the sky in Constantinople". The second aurora observation  
127 was recorded by Theophanes in June of 743: "In the northern sky of Constantinople, a  
128 sign was observed in the month of June" (Turtledove, 1982). The last aurora record was  
129 observed in Constantinople for 744: "In the northern sky, a sign seemed this year, and  
130 dust fell in several places" (Turtledove, 1982; Neuhäuser and Neuhäuser, 2015).

131 Harrak (1999) listed two aurorae records observed near Amida in the early 770s  
132 based on the Chronicle of Zuqnin. In the Chronicle of Zuqnin, the first observation was  
133 recorded in 771/772, Amida (Turkey): "Another sign was seen in the northern side, and its  
134 view gave evidence about the menace of God against us. It appeared at reaping time,  
135 while wrapping the whole northern side of the sky from west to east end. It was look like  
136 a green sceptre, a red one, a yellow one, and a black one. It was ascending from the  
137 ground and changing into 70 shapes, while one sceptre was emerging and another  
138 disappearing". The second observation was recorded in the Chronicle of Zuqnin in 773,  
139 Amida (Turkey): "In the month of June, on a Friday, another sign that was seen a year  
140 ago in the northern region was appeared again this year. It was on Fridays that it used to  
141 appear during these three consecutive years, stretching itself out from the eastern side to  
142 the western side. The sign would change into many shapes in such a way that as soon as

143 a green ray vanished, a red one would appear, and as soon as the yellow one vanished,  
144 a green would appear, and as soon as this one vanished, a black one would appear"  
145 (Harbak, 1999; Neuhäuser and Neuhäuser, 2015). These two observations listed by  
146 Harbak (1999) and Neuhäuser and Neuhäuser (2015) based on the Chronicle of Zuqnin  
147 were also cited by Dall'Olmo (1979) according to the *Chronique de Denys de Tell-Mahré*  
148 (Chabot, 1895) with different dating. In Constantinople, another aurora observation was  
149 recorded in 988: "A luminous star and fiery pillars seen in the northern region of the sky  
150 for some nights. They frightened the people who saw them." (Dall'Olmo, 1979).

151 Matthew of Edessa, who wrote a chronicle, described the events that occurred  
152 between the years 952 and 1136, and reported four aurora observations around the year  
153 1100 (Andreasyan, 2000). Matthew of Edessa reported the first aurora observation in the  
154 Armenian year 546 (25.02.1097–24.02.1098): "In this year, an odd and horrible signs were  
155 observed in the the northern side of the sky. No one had ever seen such an amazing  
156 omen so far. In the month of November, the sky kindled and reddened though the air was  
157 clear and quiet. The bloody sky was covered with stacks as if clustered on top of one  
158 another becoming colorful. The stacks were set to slip through in an easterly direction,  
159 dispersed after having gathered, and enveloped the large amount of the sky. Then, the  
160 dark redness such an amazing degree reached up to the middle of the sky vault. The  
161 savants and sages interpreted this phenomenon that, it was a sign of bloodshed. Actually,  
162 terrible events and disasters we included as a short story in our book were soon to be  
163 fulfilled."

164 Krey (1921) described an aurora observation during the siege of Antioch on the  
165 account of eyewitnesses and participants in the first crusade: "A great earthquake  
166 occurred on the third day before the Kalends of January (30 December 1097), and a very

167 fabulous sign was noticed in the sky. Northern part of the sky was so red that it appeared  
168 as if sun rose to inform the day in the first sight of the night". This observation was also  
169 described by Baldwin (1969): "There was an earthquake on December 30<sup>th</sup>, and a  
170 frightening display of the aurora borealis next evening, and in this way God chastised his  
171 army, so that we were intent upon the light which was rising in the darkness, yet the minds  
172 of some were so blind and abandoned that they were recalled neither from luxury nor  
173 robbery. At this time the Bishop prescribed a fast of three days and urged prayers and  
174 alms, together with a procession, upon the people; moreover, he commanded the priests  
175 to devote themselves to masses and prayers, the clerics to psalms". On the other hand,  
176 another aurora was observed on 3 June 1098 at Antioch based on the Link (1962) catalog  
177 as a fiery red sky (Silverman, 2006).

178 The Matthew of Edessa recorded second aurora observation in the Armenian year  
179 547 (25.02.1098–24.02.1099). "In the same year, a new sign appeared in the northern  
180 part of the sky. At the fourth hour of the night, the sky appeared more inflamed than before,  
181 and a dark red color. This phenomenon lasted from the evening until the fourth hour of  
182 the night. Such a terrible omen had never been seen so far. This omen raised upwards  
183 gradually and covered the northern portion of the sky with the lines reaching the hills. All  
184 stars took a fiery color. This phenomenon was an omen of rage and catastrophe"  
185 (Andreasyan, 2000). Botley (1964) reported an auroral observation in Antioch as a blaze  
186 of light girdled Pole. Link (1962) dated this observation on September 27, 1098.

187 In the Armenian year 548 (25.02.1099–24.02.1100) Matthew reported another  
188 aurora observation: "A fiery sign of dark red color appeared in the sky in this year. This  
189 omen heading from the northern to the eastern part of the sky appeared until the seventh  
190 hour of the night and then became black. It was said that this phenomenon was a sign of

191 bloodshed of Christians. These predictions were truly realized. No favorable omen did not  
192 appear since the day when the Franks began their expedition. All omens, however,  
193 marked to realize the destruction, death, slaughter, famine and other diverse disasters”  
194 (Andreasyan, 2000).

195 Matthew recorded the last aurora observation in the Armenian year 549  
196 (25.02.1100–24.02.1101): “The northern part of the sky flushed red for the fourth time in  
197 this year. The fiery red omen appeared more horrific than the previous one and  
198 subsequently changed into black. This fourth appearance coincided with a lunar eclipse.  
199 This phenomenon was a sign of the celestial wrath of God over the Christians as  
200 previously said by the prophet Jeremiah with these words: “His wrath will blaze up from  
201 the northern part of the sky. Indeed, several misfortunes occurred as we never could have  
202 expected” (Andreasyan, 2000).

203 Dall'Olmo (1979) reported an aurora observation based on the Chronicle of Michael  
204 the Syrian translated into French by Chabot (1968): “In the year 1108, a light like the  
205 sunlight was seen in the middle of the night, and remained about three hours in Djihan  
206 region near Adana”. Dall'Olmo (1979) was also cited 12 auroral records observed  
207 probably in the Middle East from 745 to 1141 (Table 4) according to the Chronicle of  
208 Michael the Syrian (Chabot, 1968).

209 On December 16, 1117, an aurora was recorded in Asia Minor (Link, 1962). In the  
210 same date, two observations were also reported in the Middle East (Newton, 1972) and  
211 in Palestine (Botley, 1964). These two observations could be same event. Link (1962)  
212 described other observations in Asia Minor in the year 1119. This event might be the same  
213 record observed in Armenia (Botley, 1964) given in Table 4.

214 Priest Grigor, who continued the Matthew's Chronicle and recorded events for the  
215 years 1136/37-1162/63, added one aurora observation in about the year 1143. In the  
216 Armenian year 592 (14.02.1143-13.02.1144) Priest Grigor described the aurora  
217 observation: "On Holy Thursday (1 April 1143), an omen forming of a luminous column  
218 appeared in the northern portion of the sky. This omen was visible for eight days. Three  
219 sovereigns died after the appearance of this phenomenon" (Andreasyan, 2000).

220

### 221 **3. Results and Discussions**

222 The main purpose of this study is to present an aurora catalog for the Anatolia  
223 during the medieval period. Twenty-three different historical aurora records are presented  
224 during the medieval period in Anatolia (Table 2). Another aurora catalog containing 45  
225 records collected from different sources is also given (Le Strange, 1890; Link, 1962;  
226 Botley, 1964; Newton, 1972; Dall'Olmo, 1979; Silverman, 1998; Basurah, 2006) for the  
227 Middle East region (Table 4). The aurorae were generally seen in the northern and eastern  
228 part of the sky. The color of the aurora observations was red, green, yellow and black  
229 depending on the height and relative concentrations of the nitrogen and oxygen  
230 compounds in the atmosphere (Eather, 1980).

231 The aurora records strongly correlated to high solar activity (Siscoe, 1980) provide  
232 some information about the Sun-Earth interaction as previously proved by Scafetta  
233 (2012). They are the longest direct observational records available for studying solar and  
234 space weather dynamics. Stronger solar dynamics were realized in aurorae with color  
235 green-yellow-red as seen in 772 and 773 in Amida. Miyake et al. (2012) and Usoskin et  
236 al. (2013) confirmed the 770s high solar events presenting  $^{14}\text{C}$  measurements from the  
237 annual rings of the cedar trees in Japan and inappropriate carbon cycle model in German

238 oak, respectively. The auroral records have also proven itself to be a valuable data source  
239 for the investigation of the secular variation of solar activity. Paleomagnetic researchs  
240 demonstrate that the recent dipole strength was nearly 50% weaker than it was 2500  
241 years ago (Raspopov et al., 2003). Siscoe and Siebert (2002) indicated that the dipole  
242 strength was 1.5 times as large as that of the present value. The position of the  
243 geomagnetic latitude and dipole moment might be the reason of observing aurorae in  
244 Anatolia so frequently. The average dipole moment for 750 and 1250 are  $8.85 \cdot 10^{22} \text{ Am}^2$   
245 and  $8.90 \cdot 10^{22} \text{ Am}^2$  slightly higher than the present value of  $7.78 \cdot 10^{22} \text{ Am}^2$  (Korte and  
246 Constable, 2005; Gallet et al., 2005). According to the Kawai et al. (1965) the axis of  
247 geomagnetic dipole could have inclined towards Asia at around the 11<sup>th</sup>-12<sup>th</sup> centuries. In  
248 addition, the possibility of auroral occurrence at low latitudes could demonstrate changes  
249 in the location of the North magnetic pole (Silverman, 1998).

250 The position of the magnetic poles is the most important factor defining whether  
251 the aurora was observed at a geographic region. Palaeomagnetic data provides similar  
252 longitude values ( $85^\circ \text{ N}$ ,  $115^\circ \text{ E}$ ) for the north geomagnetic pole (Merrill and McElhinny,  
253 1983). The positions of the north magnetic pole have changed from  $10^\circ \text{ N}$  to  $358^\circ \text{ N}$  in  
254 longitude and between  $79^\circ \text{ E}$  and  $88^\circ \text{ E}$  in latitude over the past 2500 years (Ohno and  
255 Hamano, 1992). During the interval of 1127–1129, the north geomagnetic pole was  
256 located at a geographic latitude of  $80^\circ \text{ N}$ , and geographic longitudes including East Asia  
257 (Merrill and McElhinny, 1983; Constable et al., 2000). According to the Fukushima (1994),  
258 the north magnetic pole was located at  $81^\circ \text{ N}$  in the eastern hemisphere near East Asia  
259 ( $100^\circ \text{ E}$  to  $130^\circ \text{ E}$ ) in the medieval period. The north geomagnetic pole of dipole axis

260 computed from the average spherical harmonic models were  $84.8^{\circ}$  N and  $103.8^{\circ}$  E in  
261 1100 (Constable et al., 2000).

262 The geomagnetic latitude of Amida (Turkey) in the late 8<sup>th</sup> century to be about  $50.1^{\circ}$   
263 N (Neuhäuser and Neuhäuser, 2015) based on the Holocene geomagnetic field (Nilsson  
264 et al., 2014) and  $45^{\circ}$  N (Hayakawa et al., 2017) based on the location of the North  
265 Geomagnetic Pole over the past 2000 years (Merrill and McElhinny, 1983). According to  
266 the Silverman (2006), the geomagnetic latitude of Edessa and Antioch was  $41^{\circ}$  N and  $40^{\circ}$   
267 N, respectively. Strong geomagnetic storms, indicating strong solar activity around 770  
268 and 1100 should have been exist in Amida ( $45^{\circ}$  N), Edessa ( $41^{\circ}$  N) and Antioch ( $40^{\circ}$ ).

269 This study could also be significant constraints for exploration of solar activity on  
270 Earth's atmosphere and climate during the historical periods previously proved by Bard  
271 and Frank (2006). According to the Bard and Frank (2006) solar fluctuations caused  
272 climatic changes called Medieval Warm Period (900–1400). The Maunder Minimum  
273 (1645-1715) is depicted by a solar activity reduction, as well as a sunspots scarcity. The  
274 Medieval Climate Anomaly characterizing by warmer and drier climate conditions  
275 generally related to reasonably prolonged solar activity during the 12<sup>th</sup> and 13<sup>th</sup> centuries  
276 (Jirikowic and Damon, 1994). Damon and Jirikowic (1992) estimated that the rise of global  
277 temperature maxima stays below  $0.8^{\circ}\text{C}$  and anomalously high temperatures pursue  
278 during the 12<sup>th</sup> and 13<sup>th</sup> centuries. Sharma (2002) revisited the issue and proposed that  
279 very large solar variations have modulated climate over the past 200 millennia. Gallet et  
280 al. (2006) demonstrated that fluctuations in the geomagnetic field might trigger significant  
281 climate change impacting on some major societal events in the Middle East at longer time.  
282 Also, climate change was a significant component to indicate the Byzantium socio-

283 economic instability during the Medieval Climate Anomaly. The fall of Constantinople in  
284 AD 1204 coincides with a lowest Auroral acitivity in a moderately wet climate condition.  
285 The moderately wet climate condition and high aurora activity around 1100 might be more  
286 likely to cause the socio-economic growth in Anatolia. Xoplaki et al. (2016) examine the  
287 relationship between the climate change and socio-economic development in Byzantine  
288 Anatolia. An inverse relationship amidst the aurora records, severe winter and famine is  
289 estimated during the years of 1100 in Anatolia. The high aurora activity could be reason  
290 of temperature rise during the medieval period in Anatolia. A new low sunspot number  
291 and lower aurora activity, which occurring in the period between 2014 and 2025 (Li et al.,  
292 2018), might have led to a temporary change in natural environment influencing the  
293 general public's attitudes and socio-economic factors. Also, resource scarcity and  
294 disparities could also lead to social tensions in the communities in the future.

295 Haldon et al. (2014) subdivided Medieval into four climatic phases as dry (270-  
296 540), very wet (540-750), moderately dry (750-950) and moderately wet (950-1400)  
297 depending on archaeological, environmental, climate, high resolution pollen and stable  
298 isotope data from sites in central and northwestern Turkey. However, this subdivision  
299 should be revised as dry (0-560), very wet (560-725), moderately dry (725-990) and  
300 moderately wet (990-1400) as given in Table 5 by using Anatolian and Middle Eastern  
301 aurora observations besides historical-climatological data. Affective cold winter, wet  
302 climate conditions, drought and famine could be occurred for Asia Minor and Middle East  
303 region during 990-1400. It seems that the relatively high auroral activity during the years  
304 around 1100 both in Anatolia and Middle East indicates that solar activity must have been  
305 intense rather than moderate causing the climate warmer (Fig. 2). In this period, Islamic  
306 world was converted into an enlightened center for science, education, medicine, and

307 philosophy as previously stated by Hamilton (1982). An important increase in agricultural  
308 production and population seems to have occurred in Anatolia after the year of 1100  
309 where the aurora observations are intense (Fig. 2). Vaquero and Trigo (2012) stated the  
310 period from 1095 to 1204 as an average solar cycle length. Vaquero et al. (1997) found a  
311 250-year cycle in naked eye sunspot observations related to intense solar activity at  
312 around 1100 comparing with aurora events being observed at mid-latitudes during the  
313 Medieval Climate Anomaly (Willis and Stephenson, 2001) and historical documents.  
314 Miyahara et al. (2008) revealed that the impact of solar variations on climate change is  
315 permanent investigating the sun-climate relationship using the  $^{14}\text{C}$  content in tree-rings  
316 during the Maunder Minimum and the Medieval Maximum Period. Bekli et al. (2017)  
317 demonstrated that the naked-eye sun spot observations from 974 to 1278 and aurora  
318 records from 965 to 1273 show multiple unusual peaks related to the high solar activity  
319 at latitudes below  $45^{\circ}$  N by using Chinese and Korean historical sources. The high aurora  
320 activity events associated with great magnetic storms occurred around the maximum  
321 phase of solar cycles rather than around the minimum (Kataoka et al., 2017).

322 In the medieval period, the people thought that the aurora was a sign of anger of  
323 God, menace, threat, apocalyptic, doomsday, misfortunes, war, slaughter and blodshed.  
324 Little (2007) described an aurora observation record in Constantinople at 396: "All people  
325 stacked to the church, and the place could not receive huge mass. But after that great  
326 tribulation, when God had accredited His word, the cloud began to diminish and at last  
327 disappeared. The people, freed from fear for a while, again heard that they must migrate,  
328 because the whole city would be destroyed on the next Sabbath. The whole people left

329 the city with the Emperor; no one remained in his house. The city was saved. What shall  
330 we say? adds Augustine. Was this the anger of God or rather His mercy”?

331 In the Chronicle of Zuqnin, an aurora observation recorded in 772, Amida (Turkey)  
332 was described: “Another sign was seen in the northern side, and its view gave evidence  
333 about the menace of God against us. For the intelligent person the sign indicated menace.  
334 Many people said many things about it; some said it announced bloodshed, and others  
335 said other things. But who knows the deeds of the Lord”?

336 Matthew of Edessa described the aurora phenomenon as a sign of rage,  
337 catastrophe, and celestial wrath of God over the Christians and bloodshed of Christians.  
338 Matthew of Edessa reported: “These predictions were truly realized. No favorable omen  
339 did not appear since the day when the Franks began their expedition. All omens noticed  
340 to realize the destruction, death, slaughter, famine and other diverse disasters”  
341 (Andreasyan, 2000).

342

#### 343 **4. Conclusions**

344 This study establishing the strong solar activity during medieval period reports the  
345 aurora observations recorded both in Anatolia and Middle East region integrating  
346 historical-climatological data. The following conclusions can be summarized as follows:

347 1. Historical Anatolian Aurora catalog (hAAc) containing 23 different aurora records  
348 provide important information on variations in the geomagnetic field and auroral  
349 activity during medieval period.

350 2. In Anatolia and Middle East, there was a relatively high auroral activity during the  
351 years around 1100 is quite consistent with the naked-eye sunspot observations  
352 related to solar activity as stated by Vaquero et al. (1997) and Bekli et al. (2017).

3. The historical Anatolian Aurora catalog exceptionally promote that there is a remarkable correlation between the past solar activity and aurora activity.
4. The solar activity, intensity of dipole moment and position of the geomagnetic pole might be the most important factors observing aurorae in Anatolia and Middle East regions during medieval period.
5. In the Medieval period, four climatic phases portrayed by Haldon et al. (2014) is revised as dry (0-560), very wet (560-725), moderately dry (725-990) and moderately wet (990-1400) depending on aurora observations besides historical-climatological data.
6. People in medieval Anatolia were believed that the aurora was a sign of celestial wrath of God, menace, threat, apocalyptic, doomsday, misfortunes, war, slaughter, rage, catastrophe and bloodshed.
7. The high and low auroral events associated with solar activity variations provide substantial use of knowledge to design and alleviate the space weather hazards in future.

## 5. Acknowledgements

I would like to thank Elif KARSLI (KTU), Alam KHAN (GU), Dr. José Valentin BAGESTON and anonymous referees for their thorough critical and constructive comments. The author is grateful to Dr. Igo PAULINO for his advice to improve the quality of this manuscript.

566 study.

567 **Table 3.** The number of historical aurora records observed in Anatolia.

568 **Table 4.** Ancient aurora observations recorded in Middle East region during medieval  
569 period.

570 **Table 5.** Summary of Ancient climate change based on the aurora observations and  
571 meterological data in Anatolia during medieval period.

572

573 **FIGURE CAPTIONS:**

574 **Figure 1.** The location map of the historical Anatolian records during medieval period.  
575 Byzantine Empire map: <https://www.britannica.com/place/Byzantine-Empire>,  
576 last access: 12 November 2019.

577 **Figure 2.** Comparison of historical aurora observations with climate change and  
578 climatological data in Anatolia and neigbouring regions. The upper panel shows  
579 the historical data climatic subdivisions, the middle panel shows the aurora  
580 observations in Anatolia and Middle East regions and the lower panel shows the  
581 land use and population in Anatolia. Historical-climatological and land use data  
582 are taken from Haldon et al. (2014).

583 **Figure 3.** The number of aurorae records per century observed in the Anatolia and in  
584 Middle East.
