Abstract. In the study of coupling processes acting within the upper atmosphere, a major challenge remains in quantifying the transformation of energy. One of the energy pathways between the ionospheric heights and the magnetosphere is the diversion of the cross-tail electric current into the ionosphere through the current wedge. This study suggests that the fact of current wedge emergence may be quantified in the case of a two-step geospace storm observed with ground-based magnetometers. The paper examines, for the first time, the latitudinal dependence of variations in the geomagnetic field on the surface of the Earth on the global scale during the severe two-step geomagnetic storm of 23–24 April 2023, a major two-step storm in solar cycle 25. The data available at INTERMAGNET magnetometer network URL ([https://imag-data.bgs.ac.uk/GIN\\_V1/GINForms2](https://imag-data.bgs.ac.uk/GIN_V1/GINForms2)) were chosen for two near-meridional chains of stations, one in the western (eight stations) and the other in the eastern (ten stations) hemispheres, which were situated, for the first time, in such a way that one of them was in the night hemisphere during both of the two steps of the geomagnetic storm. One of the most interesting observations made shows that during one step of the two-step storm part of the near-Earth cross-tail current closed itself via the ionosphere, to which it was linked by the substorm current wedge, and manifested itself in the magnetograms acquired at high and equatorial latitude stations on the night side of the Earth. The two-step character of this storm has allowed us to suggest that the  $B_z$  interplanetary magnetic field component threshold for the formation of the substorm current wedge lies in the  $-(22-30)$  nT interval. Other features of this two-step storm include the following. In the western hemisphere, the fluctuations of the geomagnetic field strength on the days used as a quiet time reference period usually did not exceed a few tens of nanotesla (nT), whereas in the course of the disturbed days, the variations in the geomagnetic field strength increased by a factor of 2 to 10 and reached a few hundred nT. In the eastern hemisphere during quiet times, the middle and low latitude magnetometer stations generally recorded strength fluctuations smaller than 10–20 nT, while during the disturbed period the fluctuations increased by a factor of 2–5 and greater, attaining  $\pm(50-70)$  nT. The strength fluctuations showed a considerable, up to 300–700 nT, increase at high latitudes. The northward component of the geomagnetic field,  $X$ , exhibited the greatest perturbations at all latitudes in both hemispheres, as the level of strength fluctuations decreased with decreasing latitude. The geomagnetic field strength fluctuations recorded at the magnetometer stations nearly-equidistant from the equator were observed to be close in magnitude. Close in value also were the strength fluctuations observed with the stations at close latitudes but in different hemispheres.

## 35 1 Introduction

36 Solar storms accompanied by solar flares, coronal mass ejections, the generation of shocks associated with coronal  
37 mass ejections or fast solar wind streams, act to generate a complex set of processes in the solar-terrestrial system  
38 comprised of the sun, interplanetary medium, magnetosphere, ionosphere, atmosphere, and solid earth to produce  
39 geospace storms or to cause significant variations in space weather. A geospace storm includes synergetically  
40 interacting storms in the magnetic field (geomagnetic storms), in the ionosphere (ionospheric storms), in  
41 thermospheric neutral density variations, earlier termed the thermospheric storms (see, e.g., (Pröls and Roemer,  
42 1987)), in the electric field in the magnetosphere, ionosphere, and atmosphere (electrical storms) (see, e.g.,  
43 (Kleimenova et al., 2008; Chernogor and Domnin, 2014; Kleimenova et al., 2017; Chernogor, 2021a). Geospace  
44 storms actually constitute the state of space weather. Space weather can have adverse effects on ground systems,  
45 such as radars or power lines (effects involving magnetic-storm-induced geoelectrical currents), or space-, air-, and  
46 ground-based communication links. The latter include errors in Global Positioning System and VLF navigation  
47 systems, loss of HF communications, disruption of UHF satellite links due to scintillations, etc. Disturbances appear  
48 in all ranges of radio waves, from VLF to UHF. Thus, many of humankind's technological systems are susceptible  
49 to failure or unreliable performance because of geospace storms, and therefore the study of the manifestations of  
50 geospace storms in all geospheres and geophysical fields remains an important task.

51  
52 The manifestations of geomagnetic storms have been studied better than those of the other kinds of storms. They are  
53 dealt with in a large number of studies concerned with a major challenge to quantify the energetics of magnetic  
54 storms (see, e.g., (Gonzalez et al., 1994)), the geomagnetic storm effects within the altitude range from the Earth's  
55 surface to 100km at midlatitudes (see, e.g., (Laštovička, 1996)), the thermospheric response to geomagnetic activity  
56 on a global scale (see, e.g., (Fuller-Rowell et al. (1997) and Buonsanto (1999))), the ionospheric response to  
57 magnetic storms (see, e.g., (Danilov and Laštovička, 2001)), the dynamic processes in the ionosphere during  
58 magnetic storms from the Kharkov incoherent scatter radar observations (Chernogor et al., 2007), the statistical  
59 characteristics of geomagnetic storms in the 24th cycle (Chernogor, 2021b), the origin of dawnside subauroral  
60 polarization streams during major geomagnetic storms (Lin et al., 2022), the simulation of a total of 122 storms  
61 ground magnetic variations, from the period 2010–2019, which has shown that high-latitude regional disturbances  
62 are still difficult to predict (Al Shidi et al., 2022), and nonlinearities in the ionosphere and thermosphere response to  
63 forcing uncertainties (Hsu and Pedatella, 2023). Since a myriad of geomagnetic storm manifestations may be  
64 observed, these issues have been summarized from time to time in books. They include a comprehensive discussion  
65 of ionospheric *F*-region storms (Pröls, 1995); the most recent developments in space weather (Daglis, 2001); a  
66 comprehensive overview of space weather (Song et al., 2001); scientific background of space storms for explaining  
67 magnetic storms on earth (Bothmer and Daglis, 2006); the importance of the tail current (Kamide and Maltsev,  
68 2007); key concepts of space weather (Moldwin, 2022); and the current state of the art in the field of space storms  
69 (Koskinen, 2011). The main concern was to study the most severe storms, since they have the strongest impact on  
70 human well-being and the correct functioning of space- and ground-based systems and can affect human health. The  
71 latter include space weather, which can endanger human life or health directly (e.g., (Daglis, 2001; Song et al.,

72 2001)); biological impacts of space storms (Bothmer and Daglis, 2006), and the perils of living in space generally  
73 (Moldwin, 2022).

74

75 Only one of many magnetic storms, a solar cycle 24 major storm of September 2017, was concerned with in dozens  
76 of studies, which were devoted to geomagnetic storm effects on the thermosphere and ionosphere (see, e.g., (Qian et  
77 al., 2019); latitudinal dependence of quasi-periodic variations in the geomagnetic field Chernogor and Shevelev,  
78 2020); negative ionospheric response over the European sector (Oikonomou et al., 2022); ionospheric storm over the  
79 Brazilian and African longitudes (Fagundes et al., 2023)). Examples of other magnetic storms that occurred over  
80 2016–2022 include physics of geospace storms (Chernogor, 2021a); the statistical characteristics of geomagnetic  
81 storms in the 24th cycle of solar activity (Chernogor, 2021b); the effects of the strong ionospheric storm of August  
82 26, 2018 as captured with multipath radio wave monitoring (Chernogor et al., 2021); the incoherent scatter radar and  
83 ionosonde observations of the ionospheric storm of 21–24 December 2016 (Katsko et al., 2021); the influence on  
84 high frequency radio wave characteristics of dynamic processes in the magnetic field and in the ionosphere during  
85 the 30 August-2 September 2019 geospace storm (Luo et al., 2021a); the geospace storm effects on 5–6 August  
86 2019 (Luo et al., 2021b); magneto-ionospheric effects of the geospace storm of 21–23 March 2017 (Luo et al.,  
87 2022); characteristic features of the magnetic and ionospheric storms of 21–24 December 2016 (Luo and  
88 Chernogor, 2022); thermospheric temperature and density variability during the 3–4 February 2022 minor  
89 geomagnetic storm (Laskar et al., 2023). The statistical analysis of geomagnetic storm effects can be found in  
90 (Chernogor, 2021b; Abe et al., 2023; De Abreu et al., 2023).

91

92 The study of geomagnetic storms remains one of the main problems in space physics. This occurs for a few reasons.  
93 First, every magnetic storm has its own individual features, in addition to the general characteristics. Second, the  
94 manifestation of magnetic storms is dependent on the solar storm parameters and features, the general state of space  
95 weather, geographic coordinates, local time, and solar cycle phase. The purpose of this paper is to analyze  
96 characteristic features of latitudinal manifestations of the 23–24 April 2023 geomagnetic storm, a major two-step  
97 storm in solar cycle 25 to date. The main features of the coronal mass ejection that caused this two-step storm can be  
98 summarized as follows (Ghag et al., 2024). First, the storm lacked sudden storm commencement. Instead, the  
99 interplanetary magnetic field  $B_z$  component turned southward at 17:37 UT on 23 April 2023 and remained negative  
100 for about three hours, after which  $B_z$  was fluctuating during the sheat transit till almost 01:00 UT on 24 April 2023  
101 with  $B_z \sim -22$  nT (<https://spaceweather.com/images2023/25apr23/cmeimpact.jpg> ). This process was the likely cause  
102 of the first step of the severe geomagnetic storm. Next, a magnetic cloud transit occurred, with  $B_z \sim -30$  nT, which  
103 was the cause of the second step of the storm under study. The two magnetometer chains employed in this study  
104 were chosen, for the first time, in such a way that one of them was in the night hemisphere of the Earth during both  
105 of the two steps of the 23–24 April 2023 geomagnetic storm.

106

107 The paper begins with a description of the data being analyzed and the state of space weather. Next, the main results  
108 of data analysis presented in Appendix in detail are summarized, and the principle achievement of this study, the

109 diversion of the cross-tail current into the ionosphere through a current wedge, is indicated. The paper ends with a  
 110 discussion of the results obtained and conclusions drawn.

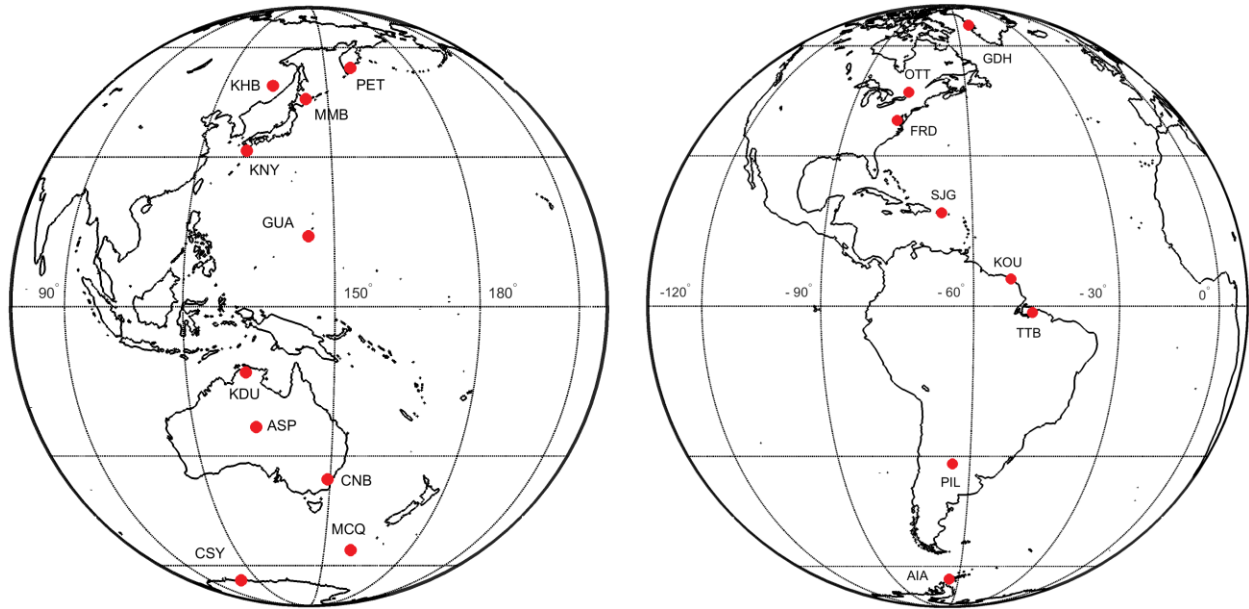

111 **2 Data and materials**

112 The data available at INTERMAGNET magnetometer network URL ([https://imag-](https://imag-data.bgs.ac.uk/GIN_VI/GINForms2)  
 113 [data.bgs.ac.uk/GIN\\_VI/GINForms2](https://imag-data.bgs.ac.uk/GIN_VI/GINForms2); retrieved 22 November 2023) from two near-meridional chains of stations, one  
 114 in the western (eight stations) and the other in the eastern (ten stations) hemispheres, have been retrieved (Fig. 1).

115 The vector magnetometers acquire measurements with 0.1-nanotesla (nT) strength resolution at a sampling rate of  
 116 one sample per second. The observatories in the western hemisphere are listed in Table 1 and those in the eastern  
 117 hemisphere are presented in Table 2. Analysis of temporal variations in the strength of the northward, X, eastward,  
 118 Y, and vertical, Z, components of the geomagnetic field over the period 20–26 April 2023 has been performed.

119

120 The data processing technique is as follows. First, the data on the absolute value of time variations are used to  
 121 calculate the diurnal trend. Then, the diurnal trend is subtracted from the primary time series resulting in the time  
 122 series of relative magnitudes. The relative magnitudes of variations in all components of the geomagnetic field are  
 123 subjected to further analysis.

124

### 134 3 Space weather

135 The data involved in the analysis of space weather include the temporal variations of solar wind parameters  
136 (<https://omniweb.gsfc.nasa.gov/form/dx1.html>), the interplanetary magnetic field (IMF), the storm-time variation,  
137  $D_{st}$ , and the three-hour planetary,  $K_p$ , indices (<https://wdc.kugi.kyoto-u.ac.jp/>), as well as calculated solar wind  
138 dynamic pressure and the Akasofu energy function, all of which are presented in Fig. 2.

139

140 During the 23–24 April 2023 storm, the solar wind showed a peak in the proton density of  $21.1 \times 10^6 \text{ m}^{-3}$  from a  
141 background of  $(5\text{--}10) \times 10^6 \text{ m}^{-3}$ , when the solar wind speed exhibited an enhancement to 706 km/s from a  
142 background of 350–400 km/s observed prior to the storm. These enhancements were accompanied by a rise in the  
143 dynamic pressure of 11 nPa from a background of 1–3 nPa, and by an increase in the temperature of  $20.5 \times 10^5 \text{ K}$   
144 from a background of  $(1\text{--}2) \times 10^5 \text{ K}$ . Under quiet conditions, the strengths of the IMF  $B_y$  and  $B_z$  components usually  
145 did not exceed  $\pm 5 \text{ nT}$ , whereas they significantly increased on 23 and 24 April 2023, with  $B_{y\text{max}} \approx 9.5 \text{ nT}$ ,  $B_{y\text{min}} \approx -$   
146  $30.2 \text{ nT}$ ,  $B_{z\text{max}} \approx 10.5 \text{ nT}$ , and  $B_{z\text{min}} \approx -32.4 \text{ nT}$ . In the course of the magnetically quiet period, the Akasofu function  
147 was smaller than 10 GJ/s, whereas two large peaks of up to 220 GJ/s and 160 GJ/s were observed to persist for 14 h  
148 and 7 h, respectively, during 23 and 24 April 2023.

149

150 The magnitude of the background  $K_p$  index varied from 0 to 3, whereas it increased from 4 to 8.3 after 12:00 UT on  
151 23 April 2023 and further decreased to 4. Yet another increase in the  $K_p$  index, up to 8, was observed between 03:00  
152 UT and 06:00 UT on 24 April 2023. Before 08:00 UT on 23 April 2023, the magnitude of  $D_{st}$  varied from  $-30$  nT to  
153 5 nT. Over the interval  $\sim 18:00$  UT on 23 April 2023 to  $\sim 01:00$  UT on 24 April 2023, the  $D_{st}$  index showed a  
154 minimum of about  $-170$  nT, and it exhibited a new decrease of approximately  $-212$  nT between  $\sim 01:00$  UT and  
155  $\sim 06:00$  UT on 24 April 2023. After the latter, the  $D_{st}$  index increased from  $-212$  nT to  $-25$  nT. Thus, this storm is  
156 the first in solar cycle 25 two-step severe geomagnetic storm with onset at 19:26 UT on 23 April 2023, which was  
157 caused by a coronal mass ejection (Ghag et al., 2024).

158  
 159 Figure 2: UT variations in the solar wind parameters: measured proton number density,  $n_{sw}$ , temperature,  
 160  $T_{sw}$ , plasma flow speed,  $V_{sw}$ , calculated dynamic pressure,  $p_{sw}$ , measured  $B_z$  and  $B_y$  components of the  
 161 interplanetary magnetic field; variations of the calculated magnitude of the energy,  $\epsilon_A$ , deposited into the  
 162 Earth's magnetosphere from the solar wind per unit time;  $K_p$ - and  $D_{st}$  indices for the period April 21 – 27,  
 163 2023 (retrieved from <https://omniweb.gsfc.nasa.gov/form/dx1.html>; last access: 14 November 2023). Dates are  
 164 indicated at the top of the figure.

165 **4 Data analysis**

166 Figs A.1–A.9 in Appendix show UT variations in the relative strength of the northward *X*-, eastward *Y*-, and vertical  
 167 *Z*-component of the geomagnetic field over the period 20–26 April 2023, within which the two-step geospace storm  
 168 occurred on 23–24 April 2023. The variations in the relative strength of the three geomagnetic field components are  
 169 analyzed in detail in Appendix and the results are summarized in Tables 3 and 4. Table 3 shows peak-to-peak  
 170 amplitude of the strength fluctuations in the geomagnetic field components recorded at the stations in the western  
 171 hemisphere, and Table 4 gives peak-to-peak amplitude of the strength fluctuations in the geomagnetic field  
 172 components recorded at the stations in the eastern hemisphere. The data presented in Fig. 3 reveal that part of the  
 173 cross-tail current is diverted into the polar ionosphere through the substorm current wedge.

174 **5 Discussion**

175 An analysis of these data show that all geomagnetic field components were a maximum during two time intervals,  
 176 one from approximately 12:00 UT to 21:00 UT on 23 April 2023 and the other from 01:00 UT to 05:00 UT on 24  
 177 April 2023. Thus, this was a two-step severe geomagnetic storm in solar cycle 25 (Ghag et al., 2024), with the  $K_p$   
 178 indices of 8.3 and 7.7, and the  $D_{st}$  index equal to  $-170$  nT and  $-212$  nT, which is the **main** characteristic feature of  
 179 the storm.

180 Substituting the solar wind dynamic pressure of 11 nPa and 10 nPa recorded for these two storms (Fig. 2) into the  
 181 expression for the energy of the magnetic storm (Gonzalez et al., 1994) yields 8.1 PJ and 9.7 PJ, with the power of  
 182 these storms of 173 GW and 674 GW, respectively. According to NOAA (<https://www.swpc.noaa.gov>), these  
 183 storms are classified as G4 (severe) geomagnetic storms. This is the second characteristic feature of the storm.  
 184

185 In the western hemisphere, the geomagnetic storm started by day on 23 April 2023, continued through the 23/24  
 186 April 2023 night, and ceased in the daytime on 24 April 2023. In the eastern hemisphere, the storm appeared during  
 187 local nighttime on 23/24 April 2023 and continued by day and at night on 24 April 2023.  
 188

189 Next consider the latitudinal dependence of the geomagnetic perturbations that occurred in the course of the storm.  
 190 The latitudinal distribution of perturbations in the strength of all geomagnetic field components on the disturbed  
 191 days and the days used as a quiet time reference period for the western and eastern hemispheres is presented in  
 192 Tables 3 and 4  
 193

194 **Table 3** Peak-to-peak amplitude of the strength fluctuations in the geomagnetic field components recorded at the stations in the  
 195 western hemisphere.

196

197 Table 3 shows that the geomagnetic field components usually exhibited variations smaller than 40–50 nT on the  
 198 days used as a quiet time reference period. In the course of the severe geomagnetic storm, the geomagnetic field  
 199 strength was observed to increase by a factor of 2–10, attaining 100–200 nT at low-latitude stations and 300–700 nT  
 200 at high-latitude stations. Table 4 shows that the middle and low latitude stations in the eastern hemisphere recorded  
 201 geomagnetic field fluctuations generally not exceeding 10–20 nT on the quiet days, whereas the storm time  
 202 fluctuations exhibited an increase by a factor of 2–5, attaining 70–80 nT; however, at high latitude stations, the  
 203 fluctuations were close to 500–600 nT. As expected, the magnitude of variations in the geomagnetic field increased  
 204 with latitude, the variations in the strength of all component recorded at the stations nearly-equidistant from the  
 205 equator were close in value, and the geomagnetic field perturbations were also close in value at close latitudes in the  
 206 western and eastern hemispheres.

207

208 **Table 4** Peak-to-peak amplitude of the strength fluctuations in the geomagnetic field components recorded at the stations in the  
 209 eastern hemisphere.

210

211 The northward component of the geomagnetic field, X, usually showed the greatest perturbations in strength in both  
 212 hemispheres. The total durations of the disturbances were observed to be 26–30 hours. Thus, the geomagnetic storm,  
 213 the strongest in solar cycle 25, being a part of the geospace storm, established the state of space weather on a global  
 214 scale over 23–24 April 2023.

215

216 Geomagnetic field variations are produced by changing electric currents. Currents relevant to geomagnetic storms  
 217 comprise the magnetopause electric current flowing eastward near the equatorial plane, the westward current  
 218 through the magnetospheric tail and equatorial ring current within 3–6 earth radius from the Earth, and the  
 219 ionospheric currents in high latitude ionosphere.

220

221 During substorms, the electric current in the near tail can partially be diverted into the polar ionosphere along the  
 222 geomagnetic field lines closing the electric current through the substorm current wedge. As a result, the westward  
 223 equatorial electric current diminishes, which should be manifested by an increase in the horizontal component of the  
 224 geomagnetic field at the equator, and the westward ionospheric current increases at high latitudes, which is observed  
 225 as an increase in the horizontal intensity,  $H$ , of the geomagnetic field. The magnetic effect on the surface of the

226 Earth from the ionospheric currents significantly surpasses that from the tail current due to the proximity of the  
227 ionosphere to the ground magnetometer stations.  
228

229 As it happened, in the observations discussed in this paper, one of the two magnetometer chain was situated in the  
230 night hemisphere of the Earth during both of the two steps of the 23–24 April 2023 geomagnetic storm. However,  
231 the anticipated manifestations of the substorm current wedge can be easily seen only during the second step of the  
232 23–24 April 2023 geomagnetic storm along the western hemisphere chain of magnetometer stations where the storm  
233 was observed during night. The  $H$  components acquired at the equatorial latitude station TTB (geomagnetic latitude  
234  $7.15^\circ\text{N}$ ) and the high geomagnetic latitude OTT (geomagnetic latitude  $54.28^\circ\text{N}$ ) station are shown in the top panel  
235 of Fig. 3. Just before 04:00 UT, a partial diversion of the ring or tail current into the ionosphere through field-  
236 aligned currents occurred and yielded an increase in the intensity of the horizontal intensity,  $H$ , of the geomagnetic  
237 field at the TTB station and a simultaneous decrease in  $H$  at high latitude OTT station. In the southern hemisphere,  
238 the northern component is also positive (Kepko et al., 2015), as can be seen in the magnetogram acquired at AIA  
239 station (Fig. 3, bottom panel).

240  
241 **Figure 3: Magnetograms from high latitude OTT and AIA stations and equatorial TTB station on the night side during**  
242 **the second step of the 23–24 April 2023 geomagnetic storm.**

243 Processes analogous to those reported above are not observed during the first step of the 23–24 April 2023  
244 geomagnetic storm along the eastern hemisphere chain of magnetometer stations where the first step of the storm  
245 was observed during night. As was described in the Introduction section, the strength of the interplanetary magnetic  
246 field  $B_z$  component attained  $\sim -22$  nT during the first step and  $\sim -30$  nT during the second step of the severe  
247 geomagnetic storm. Taking into account that the preconditioning of the sun-Earth system components and this  
248 system memory remains the same to the highest possible degree during a two-step storm, these observations suggest  
249 that there is a  $B_z$  threshold for diverting the cross-tail current through the wedge into the ionosphere, the value of  
250 which lies between  $-22$  nT and  $-30$  nT for the 23–24 April 2023 geomagnetic storm.

## 251 **6 Conclusions**

252 The intercomparisons of the geomagnetic field variations recorded at two near meridional chains of magnetometer  
253 stations in the western and eastern hemispheres yield the following results:

- 254 1. Part of the near-Earth cross-tail current closed itself via the ionosphere, to which it was linked by the substorm  
255 current wedge, and manifested itself in the magnetograms acquired at equatorial and high latitude stations on the  
256 night side of the Earth.  
257
- 258 2. The observations suggest that the  $B_z$  interplanetary magnetic field component threshold for the formation of  
259 substorm current wedge lies in the  $-(22-30)$  nT interval.  
260
- 261 3. Under quiet conditions, the geomagnetic field components usually exhibited variations not exceeding 40–50 nT in  
262 the western hemisphere and 10–20 nT in the eastern hemisphere.  
263
- 264 4. During the severe geomagnetic disturbance of 23–24 April 2023, the strength fluctuations increased by a factor of  
265 2–10 and 2–5 in the western and eastern hemispheres, respectively, attaining 300–700 nT.  
266
- 267 5. The northward component of the geomagnetic field,  $X$ , was observed to be most disturbed in the western and  
268 eastern hemispheres. The total durations of the disturbances were observed to be 26–30 hours.  
269
- 270 6. The geomagnetic field components showed variations in the strength increasing with latitude. The strength  
271 fluctuations recorded at the stations nearly-equidistant from the equator were close in value. This is true for both the  
272 western and eastern hemispheres.  
273
- 274 7. Also close in value were the perturbations in the strength recorded at the stations at close latitudes but in different  
275 hemispheres.  
276
- 277 8. The first two-step severe geomagnetic storm in solar cycle 25, as a component of the geospace storm,  
278 significantly affected the state of space weather on a global scale on 23–24 April 2023.  
279  
280

## Appendix

### Analysis of magnetometer data

Analysis of temporal variations in the relative strength of the northward  $X$ -, eastward  $Y$ -, and vertical  $Z$ -component of the geomagnetic field over the period 20–26 April 2023 has been performed. The geospace storm occurred within the period 23–24 April 2023, the data for which are shown against the background of a quiet time noise recorded during 20–22 and 25–26 April 2023.

#### A.1 Western hemisphere

*GDH Station.* From 00:00 UT to 10:00 UT over the geomagnetically quiet interval 20–22, 25, and 26 April 2023, the strength of the northward component of the geomagnetic field,  $X$ , showed fluctuations within  $\pm 50$  nT (Fig. A.1), while between 10:00 UT and 18:00 UT the strength fluctuations increased to 60–145 nT with the energy spectrum almost flat. On 23 April 2023, the variations in the  $X$ -component developed into non-monotonous and even quasi-periodic changes between 10:00 UT and 24:00 UT, when the  $X$ -component strength varied from 120 nT to 180 nT. Considerable disturbances, up to  $-550$  nT, took place at around 11:15 UT on 24 April 2023, and only after 16:00 UT on 24 April 2023 the level of fluctuations approached  $\pm 50$  nT. The recovery phase persisted for 25 and 26 April 2023.

Between 00:00 UT and 10:00 UT on 20–23 and 25, 26 April 2023, the variations in the eastward component of the geomagnetic field,  $Y$ , were relatively insignificant, up to 50 nT, while between 10:00 UT and 18:00 UT, they were observed to reach up to  $\pm 100$  nT. The variations in the  $Y$ -component showed non-monotonousness and, at times, quasi-periodicity over a span of 14 hours from 10:00 UT to 24:00 UT on 23 April 2023, with a drop in the strength down to  $-220$  nT after 19:30 UT. From 11:00 UT to 12:00 UT on 24 April 2023, the strength varied from 340 nT to  $-300$  nT.

On 20–23 and 25, 26 April 2023, the variations in the vertical component of the geomagnetic field,  $Z$ , strength were quite smooth, within  $\pm 100$  nT from 00:00 UT to 08:00 UT, while after 10:00 UT and towards the end of the day, the variations enhanced, with peak-to-peak amplitude attaining 340 nT. Between 00:00 UT and 14:00 UT on 23 April 2023, the  $Z$ -component showed significant fluctuations in strength, with peak-to-peak amplitude of 150 nT and a maximum of 100 nT. During the period 12:00 UT on 23 April 2023 to 14:00 UT on 24 April 2023, the strength variations exhibited non-monotonousness and, at times, quasi-periodicity. At about 20:00 UT on 23 April 2023, the strength reached  $-230$  nT. After 09:00 UT on 24 April 2023, the strength varied from 380 nT to  $-430$  nT, which was recorded between about 11:00 UT and 12:00 UT.

**Figure A.1:** UT variations of the geomagnetic field at the GDH station (geographic coordinates 69.2520°N, 53.5330°W, geomagnetic coordinates 77.52°N, 32.69°E) and at the OTT station (geographic coordinates 45.4030°N, 75.552°W, geomagnetic coordinates 54.46°N, 3.51°W) over the period 20–26 April 2023.

*OTT Station.* On the days used as a quiet time reference period, the variations in the strength of the northward component of the geomagnetic field,  $X$ , rarely exceeded  $\pm 20$  nT (Fig. A.1). On 23 April 2023, sharp increases of up to 250–420 nT in the strength of the  $X$ -component were observed from 19:30 UT to 22:00 UT; and from 21:00 UT to 22:30 UT, the  $X$ -component strength decreased approximately to  $-100$  nT. Between 03:00 UT and 09:30 UT on 24 April 2023, the magnetic field strength fluctuated mainly from  $-100$  nT to 200 nT, and only at 03:55 UT, it briefly dropped to  $-710$  nT. Immediately after 14:00 UT on 24 April 2023, the variations in the  $X$ -component strength became smaller than a few tens of nT.

Monotonous variations in the eastward component of the geomagnetic field,  $Y$ , strength did not exceed  $\pm 30$  nT during geomagnetically quiet times, whereas over the period 10:00 UT on 23 April 2023 to 13:00 UT on 24 April 2023, the  $Y$ -component exhibited large fluctuations in strength, from  $-125$  nT to 257 nT.

During magnetically quiet times, the vertical component of the geomagnetic field,  $Z$ , strength showed quite smooth variations, the amplitude of which was smaller than a few tens of nT. During the period 19:00 UT on 23 April 2023 to 10:00 UT on 24 April 2023, the  $Z$ -component fluctuated wildly, first from  $-140$  nT to 490 nT near 19:40 UT on 23 April 2023, then within  $\pm 80$  nT after 00:00 UT, and then it decreased to  $-560$  nT at around 03:55 UT on 24 April 2023.

*FRD Station.* The variations in the northward component of the geomagnetic field,  $X$ , did not exceed 10–15 nT during magnetically quiet times (Fig. A.2), while between about 10:00 UT on 23 April 2023 and 12:00 UT on 24 April 2023, its variations showed non-monotonousness, and an increase in  $X$ - component strength that occurred over

343 the interval 19:45–23:35 UT. The  $X$ -component exhibited fluctuations within  $-52$ – $67$  nT on 24 April 2023, with a  
344 minimum of  $-76$  nT at about 04:10 UT; after about 12:00 UT, significant variations ceased.  
345

346 During magnetically quiet times, the variations in the eastward component of the geomagnetic field,  $Y$ , strength were  
347 smaller than  $\pm 20$  nT, including the disturbance-daily variation. During a period from 10:00 UT on 23 April 2023 to  
348 13:00 UT on 24 April 2023, the strength fluctuations were large, with a minimum of  $-70$  nT that occurred between  
349 19:30–21:00 UT on 23 April 2023. An increase in the strength within  $-60$ – $115$  nT was observed to occur between  
350 02:00 UT and 12:00 UT on 24 April 2023.  
351

352 Over a span of magnetically quiet times, the vertical component of the geomagnetic field,  $Z$ , strength, weakly  
353 fluctuating, changed its magnitude by less than 5 nT. The noticeable variations in its magnitude began at around  
354 14:00 UT on 23 April 2023 and ended at about 12:00 UT on 24 April 2023, with maximums of  $\sim 44$  nT observed at  
355 around 20:00 UT and 21:00 UT on 23 April 2023, and a minimum of  $-39$  nT at about 04:00 UT on 24 April 2023.  
356

357 *SJG Station.* During magnetically quiet times, the fluctuations in strength of the northward component of the  
358 geomagnetic field,  $X$ , were smaller than  $\pm 7$  nT (Fig. A.2). The noticeable variations in strength began at around  
359 11:00 UT on 23 April 2023 and were over past 14:00 UT on 24 April 2023, with minimums of about  $-28$  nT at  
360 approximately 20:50 UT on 23 April 2023 and of about  $-42$  nT at around 04:10 UT on 24 April 2023, and with  
361 maximums of 30 nT at about 01:30 UT and 05:00 UT on 24 April 2023.  
362

363 The eastward component of the geomagnetic field,  $Y$ , strength showed insignificant variations,  $\sim 7$  nT, before 10:00  
364 UT on 20–23 and 25, 26 April 2023, while between 10:00 UT on 23 April 2023 and 14:00 UT on 24 April 2023, the  
365  $Y$ -component strength exhibited non-monotonous and significant disturbances, with a minimum of about  $-35$  nT at  
366 19:40 UT on 23 April 2023 and a maximum of about 26 nT at 07:15 UT on 24 April 2023.  
367

368 During magnetically quiet times, the vertical component of the geomagnetic field,  $Z$ , strength showed variations  
369 smaller than  $\pm 3$  nT. The non-monotonous and significant fluctuations in the strength of this component were  
370 observed to occur starting at 12:00 UT on 23 April 2023 and ending at 14:00 UT on 24 April 2023, with a minimum  
371 of about  $-11.5$  nT and a maximum of about 11.5 nT.  
372

**Figure A.2:** UT variations of the geomagnetic field at the FRD station (geographic coordinates 38.2100°N, 77.3670°W, geomagnetic coordinates 47.25°N, 5.47°W) and at the SJG station (geographic coordinates 18.1100°N, 66.1500°W, geomagnetic coordinates 27.20°N, 6.96°E) over the period 20–26 April 2023.

373  
374  
375  
376

377 *KOU Station.* During magnetically quiet times, as well as until 14:00 UT on 23 April 2023, the variations in the  
378 strength of the northward component of the geomagnetic field,  $X$ , were smaller than  $\pm 10$  nT (Fig. A.3). Over the  
379 period 11:00 UT on 23 April 2023 to 16:00 UT on 24 April 2023, the  $X$ -component showed significant  
380 enhancements in its variations that become non-monotonous, with a maximum of 35 nT at 21:00 UT on 23 April  
381 2023 and a minimum of  $-53$  nT at 04:10 UT on 24 April 2023.

382

383 During the quiet time reference period, the eastward component of the geomagnetic field,  $Y$ , exhibited variations  
384 attaining  $\pm 8$  nT, whereas its strength considerably decreased, to  $-27$  nT, at 19:40 UT on 23 April 2023, after which  
385 it increased to 52 nT at 21:30 UT. Between 00:00 UT and 12:00 UT on 24 April 2023, the  $Y$ -component showed  
386 large non-monotonous fluctuations in strength attaining  $\pm 25$  nT.

387

388 The vertical component of the geomagnetic field,  $Z$ , showed strength fluctuations usually smaller than  $\pm(5-7)$  nT,  
389 while significant time variations in strength persisted for the period 10:00 UT on 23 April to 16:00 UT on 24 April  
390 2023, with a minimum of about  $-22.5$  nT at around 14:20 UT on 23 April 2023 and a maximum of  $\sim 18$  nT at  
391 approximately 19:30 UT on the same day. During the course of the day 24 April 2023, the  $Z$ -component exhibited  
392 variations within  $-21$  nT to 19 nT.

393

**Figure A.3:** UT variations of the geomagnetic field at the KOU station (geographic coordinates  $5.2100^{\circ}\text{N}$ ,  $52.730^{\circ}\text{W}$ , geomagnetic coordinates  $13.87^{\circ}\text{N}$ ,  $20.46^{\circ}\text{E}$ ) and at the TTB station (geographic coordinates  $1.2050^{\circ}\text{S}$ ,  $48.5130^{\circ}\text{W}$ , geomagnetic coordinates  $7.25^{\circ}\text{N}$ ,  $24.35^{\circ}\text{E}$ ) over the period 20–26 April 2023.

*TTB Station.* On quiet time reference days, the northward component of the geomagnetic field,  $X$ , showed variations smaller than  $\pm 20$  nT (Fig. A.3), which developed into non-monotonous and significant variations over a span of time between  $\sim 10:00$  UT on 23 April 2023 and  $\sim 16:00$  UT on 24 April 2023. The field strength had minimums of  $-35$  nT and  $-55$  nT at  $\sim 21:00$  UT on 23 April 2023 and at  $04:10$  UT on 24 April 2023, respectively, and a maximum of  $57$  nT at  $17:40$  UT on 23 April 2023.

The quiet time eastward component of the geomagnetic field,  $Y$ , strength usually exhibited variations smaller than  $\pm 10$  nT, whereas on 23 April 2023 a minimum strength of  $-31$  nT was recorded at  $\sim 17:45$  UT and a maximum of about  $29$  nT at  $21:35$  UT on 23 April 2023. The significant variations in the  $Y$ -component persisted through to  $18:00$  UT on 24 April 2023, with a maximum of  $30$  nT at  $04:10$  UT on 24 April 2023.

During magnetically quiet times, the vertical component of the geomagnetic field,  $Z$ , exhibited variations within  $\pm 7$  nT. Approximately from  $12:00$  UT on 23 April 2023 to  $19:00$  UT on 24 April 2023, this component showed fluctuations in strength from  $-20$  nT to  $26$  nT.

*PIL Station.* On quiet time reference days, the northward component of the geomagnetic field,  $X$ , exhibited strength variability within  $\pm 10$  nT (Fig. A.4), while it showed a significant increase in non-monotonous variations over the interval  $11:00$  UT on 23 April 2023 to  $14:00$  UT on 24 April 2023. The positive spikes of  $37$  nT and  $47$  nT were observed to occur at  $17:40$  UT on 23 April 2023 and at  $\sim 04:00$  UT on 24 April 2023, respectively, while the negative spikes of  $-47$  nT and  $-68$  nT to occur at  $21:00$  UT on 23 April 2023 and at  $04:10$  UT on 24 April 2023, respectively.

420  
421 The eastward component of the geomagnetic field,  $Y$ , strength showed variability within a few nT under quiet time  
422 conditions, while from 12:00 UT on 23 April 2023 to 16:00 UT on 24 April 2023 this component variations became  
423 non-monotonous and significant, with spike strengths attaining 6.5 nT and alternating decrease strengths reaching -7  
424 nT over the interval 19:00 UT to 20:00 UT on 23 April 2023, and a drop of -10.5 nT at approximately 04:40 UT on  
425 24 April 2023.

426  
427 During magnetically quiet times, the vertical component of the geomagnetic field,  $Z$ , showed variations smaller than  
428 a few nT, whereas it exhibited considerable and sharp variations from 10:00 UT on 23 April 2023 to 16:00 UT on 24  
429 April 2023. The  $Z$ -component strength fell to -7.3 nT at approximately 04:10 UT on 24 April 2023, while its  
430 magnitude was close to 3 nT at about 16:00 UT.

431  
432 *AIA Station.* On quiet time reference days, the northward component of the geomagnetic field,  $X$ , exhibited strengths  
433 rarely exceeding  $\pm 20$  nT (Fig. A.4). The considerable and sharp variations in this component strength began at  
434 around 18:00 UT on 23 April 2023 and continued until 12:00 UT on 24 April 2023. During 23 April 2023, the  $X$ -  
435 component strength was observed to vary from -100 nT to 290 nT, while it showed greater variability on 24 April  
436 2023 when the strength varied from -380 nT to 200 nT.

437  
438 The quiet time eastward component of the geomagnetic field,  $Y$ , strength showed variability within  $\pm 30$  nT. The  
439 significant and sharp variations in the  $Y$ -component began at 13:00 UT on 23 April 2023 and persisted for 24 h. On  
440 23 April 2023, the  $Y$ -component showed strength fluctuations from -230 nT to 150 nT, which increased from -400  
441 nT to 240 nT on 24 April 2023.

442  
443 Under quiet time conditions, the vertical component of the geomagnetic field,  $Z$ , exhibited fluctuations in strength  
444 smaller than  $\pm 20$  nT. From 18:00 UT on 23 April 2023 to 13:00 UT on 24 April 2023, the strength variations were  
445 sharp and significant. The  $Z$ -component showed strength variations within -250-170 nT on 23 April 2023, and  
446 within -215-300 nT on 24 April 2023.

447

**Figure A.4:** UT variations of the geomagnetic field at the PIL station (geographic coordinates 31.6670°S, 63.881°W, geomagnetic coordinates 22.33°S, 8.08°E) and at the AIA station (geographic coordinates 65.2450°S, 64.2580°W, geomagnetic coordinates -55.91°, +6.30°) over the period 20–26 April 2023.

## A.2. Eastern Hemisphere

*PET Station.* On quiet time reference days, the northward component of the geomagnetic field,  $X$ , exhibited moderate variability within  $\pm 10$  nT (Fig. A.5). Considerable and sharp strength variations began after 10:30 UT on 23 April 2023 and persisted past 11:30 UT on 24 April 2023, with the strength fluctuating within  $-55$  nT– $43$  nT on 23 April 2023, and from  $-45$  nT to  $70$  nT on 24 April 2023.

The quiet time eastward component of the geomagnetic field,  $Y$ , strength variations were smaller than  $\pm 15$  nT. The amplitude fluctuations considerably increased past 10:00 UT on 23 April 2023 and persisted until 12:00 UT on 24 April 2023. In the course of the first day, the amplitude fluctuations in strength occurred within  $-77$  nT to  $70$  nT, while they occurred around a lower strength level, from  $-57$  nT to  $50$  nT, on the second day.

During the quiet time reference period, the vertical component of the geomagnetic field,  $Z$ , showed fluctuations in strength with amplitudes varying from about  $-7$  nT to  $6$  nT. The fluctuations notably increased after 10:00 UT on 23 April 2023 and continued until 13:00 UT on 24 April 2023. On 23 April 2023, the  $Z$ -component exhibited variations in strength from  $-28$  nT to  $18$  nT, while it showed variations from  $-15$  nT to  $29$  nT the next day.

**Figure A.5:** UT variations of the geomagnetic field at the PET station (geographic coordinates 52.9710°N, 158.2480°E, geomagnetic coordinates +46.63, +222.93) and at the KHB station (geographic coordinates 47.61°N, 134.68°E, geomagnetic coordinates 39.05°N, 156.42°W) over the period 20–26 April 2023.

*KHB Station.* On quiet time reference days, the northward component of the geomagnetic field,  $X$ , strength showed variations generally not exceeding  $\pm 10$  nT (Fig. A.5). The pronounced enhancements in sharp variations of the  $X$ -component strength began after about 11:00 UT on 23 April 2023 and continued until 16:00 UT on 24 April 2023. On 23 April 2023, the  $X$ -component strength exhibited variations within  $-50$  nT to  $40$  nT, and it showed variations from  $-30$  nT to  $50$  nT on 24 April 2023.

The quiet time eastward component of the geomagnetic field,  $Y$ , variations were observed to occur mainly within  $\pm 10$  nT, rarely attaining  $20$  nT. The amplitude fluctuations showed a noticeable increase after 10:00 UT on 23 April 2023, with the disturbance continuing through to 14:00 UT on 24 April 2023. On the first day, the  $Y$ -component showed fluctuations from  $-30$  nT to  $43$  nT, and on the second day within  $-39$  nT to  $54$  nT.

The vertical component of the geomagnetic field,  $Z$ , exhibited insignificant temporal variability within  $\pm 2$  nT on the days used as a quiet time reference period, whereas the strength was observed to increase to  $7.5$ – $12$  nT on 23 April 2023. On 24 April 2023, the component showed strength fluctuations within  $-14.5$  nT to  $7$  nT. In total, the enhanced fluctuations persisted for about 26 h.

*MMB Station.* The strengths of the northward component of the geomagnetic field,  $X$ , showed quiet time variations generally smaller than  $\pm 20$  nT, but most frequently they were confined to  $\pm 10$  nT (Fig. A.6). Enhanced variations in the  $X$ -component strength began before 10:00 UT on 23 April 2023 and continued through to 12:00 UT on 24 April 2023, with the strength of this component changing from  $-50$  nT to  $40$ – $47$  nT.

496 The quiet time variations in the eastward component of the geomagnetic field,  $Y$ , strength reached  $\pm 10$  nT.  
497 Significant variations in the  $Y$ -component strength began at about 10:00 UT on 23 April 2023 and continued through  
498 to about 13:00 UT on 24 April 2023, with the variations in this component strength not exceeding  $\pm 35$  nT on the  
499 first day, and showing temporal variability within  $\pm(30-35)$  nT on the second day.  
500

501 On the days used as a quiet time reference period, the vertical component of the geomagnetic field,  $Z$ , strength  
502 exhibited temporal variability within a few nT, whereas they noticeably increased at  $\sim 10:00$  UT on 23 April 2023  
503 and persisted until 13:00 UT on 24 April 2023, with fluctuations attaining  $\pm(10-12.5)$  nT.  
504

505 *KNY Station.* The northward component of the geomagnetic field,  $X$ , generally exhibited variations in strength  
506 smaller than  $\pm 10$  nT (Fig. A.6). The strength fluctuations showed a sharp increase after 10:00 UT on 23 April 2023  
507 and continued to 16:00 UT on 24 April 2023. On 23 April 2023, the strength exhibited variations within  $-35$  nT to  
508 31 nT, and within  $-28$  nT to 32 nT the following day.  
509

510 The quiet time variations in the eastward component of the geomagnetic field,  $Y$ , strength occurred within  $\pm 8$  nT.  
511 After 10:30 UT on 23 April 2023, the strength fluctuations increased from  $-12$  nT to 28 nT. The next day, this  
512 component strength exhibited temporal variability within  $-26$  nT to 27 nT.  
513

514 On the quiet time reference days, the vertical component of the geomagnetic field,  $Z$ , showed variations in strength  
515 from  $-6$  nT to 11 nT. The strength variations exhibited a noticeable increase after 10:00 UT on 23 April 2023 and  
516 continued through to about 16:00 UT on 24 April 2023, with the fluctuations within  $\pm 20$  nT.  
517

518 *GUA Station.* The quiet time variations in the northward component of the geomagnetic field,  $X$ , generally did not  
519 exceed 7–8 nT (Fig. A.7). Enhanced strength fluctuations were observed to occur over the interval 10:00 UT on 23  
520 April 2023 to 06:00 UT on 24 April 2023. On 23 and 24 April 2023, the strength of this component varied from  $-30$   
521 nT to 47 nT, occasionally to 70 nT.  
522

**Figure A.6:** UT variations of the geomagnetic field at the MMB station (geographic coordinates 43.91°N, 144.19°E, geomagnetic coordinates 36.09°N, 147.57°W) and at the KNY station (geographic coordinates 31.42°N, 130.88°E, geomagnetic coordinates 22.70°N, 158.28°W) over the period 20–26 April 2023.

The eastward component of the geomagnetic field,  $Y$ , exhibited fluctuations in strength within  $\pm 5$  nT on the days used as a quiet time reference period. Enhancements in the strength fluctuations occurred over the interval 10:00 UT on 23 April 2023 to 14:00 UT on 24 April 2023. On the first day, the strength of this component varied from  $-8$  nT to 12 nT, and on the second day it varied within  $-12$  nT to 13 nT. A brief  $\sim 19$ -nT drop in the strength of this component was seen at around 04:00 UT on 24 April 2023.

The vertical component generally exhibited variations in the strength smaller than a few nT. Noticeable increases in the variations of the strength of this component were observed to occur over the interval 10:00 UT on 23 April 2023 to 05:00 UT on 24 April 2023. On 23 April 2023, the  $Z$ -component strength fluctuations occurred within  $\pm 7$  nT, while the following day they exhibited variations within  $-10$  nT to 12 nT, with a brief decrease by 23 nT at about 04:00 UT.

*KDU Station.* On the days used as a quiet time reference period, the variations in the strength of the northward component of the geomagnetic field,  $X$ , were observed to occur within  $\pm 6$  nT (Fig. A.7). On 23 April 2023, the fluctuations in strength occurred within  $-42$  nT to 28 nT from 10:00 UT to 24:00 UT. From 00:00 UT to 12:00 UT the next day, the  $X$ -component exhibited variations within  $-23$  nT to 30 nT.

The eastward component of the geomagnetic field,  $Y$ , strength was observed to fluctuate within about  $-7$  nT to 6 nT on the quiet days. From 10:00 UT to 24:00 UT on 23 April 2023, the level of strength fluctuations enhanced to  $\pm 20$  nT. The following day, the  $Y$ -component strength showed variations within  $-27$  nT to 15 nT over the interval 00:00 UT to 13:00 UT.

550  
551  
552  
553  
554

Generally, the vertical component of the geomagnetic field, Z, showed variations in strength smaller than  $\pm 3$  nT. Over the interval 10:00 UT on 23 April 2023 to 05:00 UT on 24 April 2023, a noticeable increase in the level of strength fluctuations was recorded, down to  $-8$  nT and up to  $\sim 10$  nT.

555  
556

**Figure A.7:** UT variations of the geomagnetic field at the GUA station (geographic coordinates  $13.59^{\circ}\text{N}$ ,  $144.87^{\circ}\text{E}$ , geomagnetic coordinates  $6.10^{\circ}\text{N}$ ,  $143.44^{\circ}\text{W}$ ) and at the KDU station (geographic coordinates  $12.69^{\circ}\text{S}$ ,  $132.47^{\circ}\text{E}$ , geomagnetic coordinates  $20.96^{\circ}\text{S}$ ,  $153.66^{\circ}\text{W}$ ) over the period 20–26 April 2023.

562  
563  
564  
565  
566  
*ASP Station.* The northward component of the geomagnetic field, X, showed the quiet time variability of strength mainly within  $\pm(3\text{--}10)$  nT (Fig. A.8). The enhancement in strength fluctuations with peak-to-peak amplitude of  $-53$  nT to  $32$  nT was observed to occur between 10:00–24:00 UT on 23 April 2023, while between 00:00–06:00 UT the next day, the X-component strength exhibited temporal variability within  $-28$  nT to  $39$  nT.

568  
569  
570  
571  
572  
573  
574  
575  
During quiet days, the eastward component of the geomagnetic field, Y, exhibited strength variations smaller than  $\pm 10$  nT, which then significantly enhanced beginning at about 10:00 UT on 23 April 2023 and persisted until 13:00 UT on 24 April 2023. On the first day, the level of strength fluctuations was found between  $-33$  nT and  $43$  nT, while on the second day it varied from  $-44$  nT to  $15$  nT.

576  
577  
578  
579  
580  
581  
582  
583  
584  
585  
On the days used as a quiet time reference period, the vertical component of the geomagnetic field, Z, exhibited temporal variability within  $\pm 3$  nT. From 10:00 UT to 24:00 UT on 23 April 2023, the Z-component showed an increase in strength fluctuations from  $-6.5$  nT to  $5$  nT, while on the following day it exhibited fluctuations from  $-5$  nT to  $12$  nT.

576 *CNB Station*. On the quiet days, the northward component of the geomagnetic field,  $X$ , showed variations in strength  
 577 mainly from  $-10$  nT to  $10$  nT (Fig. A.8). Significant enhancements in strength began at around 10:00 UT on 23  
 578 April 2023 and continued through to 12:00 UT on 24 April 2023. The strength of this component was observed to  
 579 vary from  $-62$  nT to  $55$  nT on the first day, and within  $\pm 40$  nT from 00:00 UT to 12:00 UT on the second day.  
 580

581  
 582  
 583 **Figure A.8:** UT variations of the geomagnetic field at the ASP station (geographic coordinates  $23.76^{\circ}\text{S}$ ,  $133.88^{\circ}\text{E}$ ,  
 584 geomagnetic coordinates  $31.83^{\circ}\text{S}$ ,  $151.20^{\circ}\text{W}$ ) and at the CNB station (geographic coordinates  $35.32^{\circ}\text{S}$ ,  $149.36^{\circ}\text{E}$ ,  
 585 geomagnetic coordinates  $41.75^{\circ}\text{S}$ ,  $132.81^{\circ}\text{W}$ ) over the period 20–26 April 2023.  
 586

587 On the days used as a quiet time reference period, the eastward component of the geomagnetic field,  $Y$ , showed  
 588 strength fluctuations not exceeding  $\pm 20$  nT. Between 10:00 UT and 24:00 UT on 23 April 2023, the  $Y$ -component  
 589 exhibited variations in strength from  $-60$  nT to  $64$  nT, and during the interval 00:00 UT to 12:00 UT on 24 April  
 590 2023, from  $-95$  nT to  $43$  nT.  
 591

592 The vertical component of the geomagnetic field,  $Z$ , showed quiet time variations in strength smaller than  $\pm 8$  nT.  
 593 Considerable enhancements in sharp variations in the strength of this component began at about 10:00 UT on 23  
 594 April 2023 and persisted until 12:00 UT on 24 April 2023, with the  $Z$ -component strength varying from  $-28$  nT to  
 595  $33$  nT.  
 596

597 *MCQ Station*. On the quiet days, the northward component of the geomagnetic field,  $X$ , was observed to vary from  $-$   
 598  $40$  nT to  $70$  nT (Fig. A.9), with the exception of a decrease by  $380$  nT and an increase by  $200$  nT in strength at  
 599 around 12:00 UT on 26 April 2023, as well as decreases by  $160$  nT and  $120$  nT at around 11:00 UT and 14:00 UT on  
 600 21 and 25 April 2023, respectively. Significant and sharp increases in amplitude and frequency fluctuations began at

601 10:00 UT on 23 April 2023 and stopped at around 12:00 UT on 24 April 2023, with the strength fluctuating within –  
602 530 nT to 470 nT.

603  
604 On the days used as a quiet time reference period, the eastward component of the geomagnetic field, *Y*, showed  
605 variations in strength smaller than 30–40 nT, with the exception of a drop of about 200 nT that followed an increase  
606 by 100 nT near 12:00 UT on 26 April 2023. A significant rise in amplitude and frequency fluctuations was observed  
607 to occur after 10:00 UT on 23 April 2023 and continued until 12:00 UT on 24 April 2023, when the *Y*-component  
608 strength varied from –600 nT to 340 nT.

609  
610 Over the intervals 12:00–14:30 UT on 25 and 26 April 2023, the vertical component of the geomagnetic field, *Z*,  
611 strength exhibited variability within –80 nT to 100 nT. On 21 April 2023, the strength reached 160 nT. In the course  
612 of all other quiet days, this component showed variations not exceeding a few tens of nT. From 10:00 UT on 23  
613 April 2023 to 12:00 UT on 24 April, the *Z*-component exhibited a sharp increase in temporal variability and the  
614 level of strength fluctuations. The strength variations reached  $\pm 320$  nT.

615  
616 *CSY Station.* The northward component of the geomagnetic field, *X*, exhibited strength fluctuations generally  
617 smaller than  $\pm 50$  nT on the days used as a quiet time reference period (Fig. A.9). Sporadically, they reached  $\pm 100$   
618 nT. Significant variations began after 17:00 UT on 23 April 2023 and persisted for about 24 h. On 23 April 2023,  
619 the strength of this component showed a decrease to –150 nT and increases to 100–110 nT. In the 24 April 2023  
620 morning, the strength of this component showed variations within –100 nT to 160 nT. On the days used as a quiet  
621 time reference period, the eastward component of the geomagnetic field, *Y*, showed variations usually not exceeding  
622  $\pm(30\text{--}40)$  nT, whereas the strength fluctuations reached  $\pm 180$  nT during the storm.

623  
624 The vertical component of the geomagnetic field, *Z*, seldom exhibited variations in excess of 50 nT, with the greatest  
625 variations (–380 nT to 260 nT) seen on 23 April 2023.

626  
627 The particular attention should be given to significant, up to 300–380 nT, variations that were recorded in all  
628 components from 12:40 UT to 16:00 UT on 24 April 2023. During this UT interval, the *X*-, *Y*-, and *Z*-components  
629 exhibited strength fluctuations within –380–120 nT, –130–380 nT, and –250–290 nT, respectively.
